2 INTRODUCTION

2.1 Purpose

This is the non-proprietary FIPS 140-2 Security Policy for the McAfee Endpoint Encryption Manager cryptographic module, also referred to as "the module" within this document. This Security Policy details the secure operation of McAfee Endpoint Encryption Manager as required in Federal Information Processing Standards Publication 140-2 (FIPS 140-2) as published by the National Institute of Standards and Technology (NIST) of the United States Department of Commerce.

2.2 References

For more information on McAfee Endpoint Encryption Manager and the McAfee Endpoint Encryption product range please visit:

<u>http://www.mcafee.com/us/enterprise/products/data_loss_prevention/endpoint_encryption.html</u>. For more information on NIST and the Cryptographic Module Validation Program (CMVP), please visit <u>http://csrc.nist.gov/groups/STM/cmvp/index.html</u>.

2.3 Document Organization

This Security Policy document is one part of the FIPS 140-2 Submission Package. This document outlines the functionality provided by the module and gives high-level details on the means by which the module satisfies FIPS 140-2 requirements. With the exception of this Non-Proprietary Security Policy, the FIPS 140-2 Submission documentation may be McAfee, Inc. proprietary or otherwise controlled and releasable only under appropriate non-disclosure agreements. For access to these documents, please contact McAfee, Inc.

McAfee[®]

3 McAfee Endpoint Encryption Manager

McAfee Endpoint Encryption Manager (SW Version 5.2.6), also referred to simply as "module", is a Software Only Module, which resides on a General Purpose Computer (see Figure 1). In simple terms, McAfee Endpoint Encryption Manager is a management console application that allows an authorized Crypto Officer to manage, configure and deploy McAfee Endpoint Encryption point product software.

In order to install the module it is first necessary to install the core McAfee Endpoint Encryption Manager software (Endpoint Encryption Manager v5.2.6, file download McAfee_EEM_526.zip) and then to install the McAfee Endpoint Encryption for PC software (Endpoint Encryption for PC v5.2.6, file download McAfee_EEPC_526.zip).

The cryptographic boundary of the module is the case of the Personal Computer (PC) on which it is installed. See Figure 1. The module is a software module running on a Common Criteria EAL2 certified operating environment. The processor of this platform executes all software. All software components of the module are persistently stored within the device and, while executing, are stored in the device local RAM.

Physical boundary

Figure 1: Block Diagram of the cryptographic boundary

However, the module consists of a number of components:

- The McAfee Endpoint Encryption Manager Management Console GUI application,
- Token modules to facilitate user identification and authentication,
- The Object Directory, a central repository for system objects (Supported accessible Objects are Users, Machines, Servers, Files, Directories, and Groups),
- The McAfee Endpoint Encryption Database Server that allows McAfee Endpoint Encryption point products to connect to and synchronize with the Object Directory,
- The McAfee Endpoint Encryption Connector Manager is responsible for managing the association of information between the Endpoint Encryption Object Directory and another data source. This remote source may be another Object Directory, or may be some third party system (for example an X500 directory over LDAP, or Microsoft Active Directory).

For FIPS 140-2 purposes, all of the components of the module are installed and running on a single General Purpose Computer (GPC).

The cryptographic module meets the overall requirements applicable to Level 2 security of FIPS 140-2, with Roles, Services and Authentication, and Design Assurance at Level 3.

Security Requirements Section	Level
Cryptographic Module Specification	2
Module Ports and Interfaces	2
Roles, Services and Authentication	3
Finite State Model	2
Physical Security	N/A
Operational Environment	2
Cryptographic Key Management	2
EMI/EMC	2
Self-Tests	2
Design Assurance	3
Mitigation of Other Attacks	N/A

Figure 2: Security Level specification per individual areas of FIPS 140-2

3.1 McAfee Endpoint Encryption Manager

McAfee Endpoint Encryption Manager is a Windows GUI whose purpose is to allow McAfee Endpoint Encryption Systems to be deployed, configured and synchronized.

McAfee Endpoint Encryption Manager is able to manage a number of McAfee Endpoint Encryption products, including:

- McAfee Endpoint Encryption for PCs
- McAfee Endpoint Encryption for Files and Folders
- McAfee Endpoint Encryption for Mobile

User and Machine configurations are created and modified using McAfee Endpoint Encryption Manager and stored in a central database, the Object Directory.

Every time a Endpoint Encryption protected system starts, and optionally every time the user initiates a remote access connection or after a set period of time, Endpoint Encryption tries to contact its Object Directory.

Endpoint Encryption applications query the directory for any updates to their configuration, and if needed download and apply them. Typical updates could be a new user assigned to the machine by an administrator, a change in password policy, or an upgrade to the Endpoint Encryption operating system or a new file specified by the administrator. At the same time Endpoint Encryption uploads details like the latest audit information, any user password changes, and security breaches to the Object Directory. In this way, transparent synchronization of the enterprise becomes possible.

3.2 Module Interfaces

McAfee Endpoint Encryption Manager is classified as a multi-chip standalone module for FIPS 140-2 purposes. The module's physical boundary is that of the GPC on which it is installed. The GPC shall be running a supported operating system (OS) and supporting all standard interfaces, including keys, buttons and switches, and data ports.

McAfee Endpoint Encryption Manager provides a logical interface via a Graphical User Interface (GUI) and a secure communications channel via a TCP/IP interface with McAfee Endpoint Encryption applications. This logical interface exposes services (described in section 3.4) that the User and McAfee Endpoint Encryption applications may utilize directly.

McAfee Endpoint Encryption Manager provides a logical interface to physical tokens outside of the cryptographic boundary to provide user authentication.

The logical interfaces provided by McAfee Endpoint Encryption Manager are mapped onto the FIPS 140-2 logical interfaces: data input, data output, control input, and status output as follows:

- Data Input Input from TCP/IP interface during application synchronization, GUI, token input
- Data Output Output to TCP/IP interface during application synchronization, GUI, user authentication to physical token
- Control Input Input from TCP/IP interface, GUI
- Status Output –GUI

3.3 Operational Environment

The cryptographic module is capable of running and tested in FIPS 140-2 Level 2 mode on the following Common Criteria-evaluated platforms:

- Windows Server 2003 SP1 on Dell Optiplex GX620
- Windows Server 2008 on Dell PowerEdge 2970

Windows Server Enterprise 2008 (64 bit) and Dell PowerEdge 2970, 1.7 GHz quad core AMD Opteron 2344 Processor (2 CPUs), 64-bit http://www.commoncriteriaportal.org/files/epfiles/st_vid10291-st.pdf

Windows Server 2003 SP1 Dell Optiplex GX620 and 3.0 GHz Intel Pentium D Processor 830 (1 CPU), 32-bit

http://www.commoncriteriaportal.org/files/epfiles/20080303_st_vid10184-st.pdf

The module is also capable of running on the following platforms. However it has not been tested during this evaluation on these platforms and no compliance is being claimed for them:

- Microsoft Windows 7
- Microsoft Windows Vista 64
- Microsoft Windows XP
- Microsoft Windows Vista 32
- Microsoft Windows 2000.

The cryptographic module runs in its own operating system threads. This provides it with protection from all other processes, preventing access to all keys, intermediate key generation values, and other CSPs.

The task scheduler and architecture of the operating system maintain the integrity of the cryptographic module.

For the purposes of FIPS 140-2 validation, the module supports only one single user and only one operator can have access to the GPC that contains the module at a time. For the purposes of FIPS 140-2, each of the Windows operating systems listed above must be configured as a single user operating system.

3.4 Roles and Services

McAfee Endpoint Encryption Manager implements both a Crypto Officer role and a User role. The module provides identity-based authentication for both Users and Crypto Officers. Figure 4 summarizes the services available to each role.

Role	Description	
Crypto Officer	The administrator of the module having full configuration	
	and key management privileges.	
User	General User of the module, with only read access to the	
	objects in the directory.	
Figure 3: Roles		

Each object in the directory has a certain "administration privilege" with a range of between 1 (lowest) to 32 (root administrator), no object except the root administrator can change the attributes of an object of its privilege or above, but some attributes can be read regardless. This mechanism stops low privilege users

from changing their own configuration, and protects high-level administrators from the activities of lower levels.

For the purposes of FIPS 140-2 validation, a Crypto Officer has an administration privilege level of 32, and a User has an administration privilege level of 1. Further, the configuration of the module is required to restrict access for all Users to "View" operations, that is, read-only operations.

3.4.1 User and Crypto Officer authentication

Users and Crypto Officers logon to the module in the same way: identity-based access control and authentication using tokens.

The module supports several different types of token to provide identity based authentication.

The CAC and PIV cards and card readers are outside of the cryptographic boundary but the module provides an interface to these for authentication purposes.

The CAC and PIV smartcards are PKI tokens. Access control to the token is provided via a user name and a password, that is access to the token is password protected. Once access to the token is granted, the certificate on the token is used to decrypt an encrypted user CSP which is then used to decrypt the machine key. Each user is assigned a unique user name. Possession of the physical token, the ability to access it using a secret password, allows the module to use the token key to decrypt the user key matching the user. This provides identity based authentication of that user.

Note regarding PIV authentication:

In order to use PIV Authentication you need to do the following:

a. The full Principal Name of the user must be used in the EE MGR username field. This can be found in the PIV certificate.

b. In the file SbTokenPIV.ini file the usernametype field must be set to 0 (This is so the software checks against the full principal name).

Figure 4 summarizes the authentication mechanism for each of these roles, and Figure 5 describes the strength of these mechanisms.

Role	Type of Authentication	Authentication Data
User	Identity-based	1024 bit tokens for CAC and
		PIV are used for User and
		Crypto Officer authentication
		to the module. A password is
		used to access the token.
Crypto Officer	Identity-based	1024 bit tokens for CAC and
		PIV are used for User and
		Crypto Officer authentication
		to the module. A password is
		used to access the token.

Figure 4 Roles and Required Identification and Authentication

Authentication Mechanism	Strength of Mechanism
Password	It is possible to configure the minimum
	password length and the type of characters that
	can be used in a password. It is also possible to
	configure the client to lock up after a specified
	number of unsuccessful password entry
	attempts. If a minimum password length of 4 is
	used, and the password is restricted to
	alphanumeric characters, this gives a chance of
	success of 1 in 62^4 or 1 in 14,776,336 for
	guessing a password, which is greater than
	required. McAfee, Inc. recommends a
	minimum password length of 5 characters,
	giving a random chance of success of 1 in
	916,132,832. If 10 login attempts are possible
	in one minute, this gives a chance of
	successfully guessing the password at 1 in
	91,613,283. This is significantly better than the
	acceptable probability of 1 in 100,000.
PKI encryption	1024 bit tokens for CAC and PIV are used for
	User and Crypto Officer authentication to the
	module.

Figure 5 Strength of Authentication Mechanisms

3.5 Access to Services

The following table, Figure 4, lists the authorized services linked to each of the Roles offered by the module.

Role User	Crypto Officer	Authorized Services	Description	Service Input	Service Output
	X	Create Installation Set	Creates an installation set that contains all of the software needed to deploy the particular Endpoint Encryption point product that the installation set represents.	Crypto Officer chooses "Create Installation Set" option	Installation set
	X	Synchronization	Establishes a secure network connection between the module and a McAfee Endpoint Encryption point product for the	Synchronization request either triggered manually or according to a predetermined	Updated client module. Client module datastore synchronized

Role				Service Input	Service
User	Crypto Officer	Authorized Services	Description		Output
			purpose of configuring	policy	with Object
			the module.		Directory

3.6 Physical Security

McAfee Endpoint Encryption Manager is a software only cryptographic module and therefore the physical security requirements of FIPS 140-2 do not apply.

3.7 Cryptographic Key Management

The following tables list all Critical Security Parameters (CSPs) and public keys used within the McAfee Endpoint Encryption Manager module. Currently, AES-256 is the only Approved encryption algorithm in McAfee Endpoint Encryption Manager product and all encryption keys are AES-256 keys. The server public key is a DSA key.

Key type	Purpose
Database Key	To encrypt the Object Directory.
Machine Key	Each PC/device has a key that is used to encrypt its hard disk/data.
	This key is also used to authenticate an Endpoint Encryption point
	product to the McAfee Endpoint Encryption Manager.
User Key	To encrypt secure user attributes.
User Recovery Key	To recover the user key.
Machine Recovery Key	To recover the machine key

Key type	Purpose			
Session Key	Key used to encrypt traffic between device and remote server			
Diffie-Hellman Shared Secret	Shared secret generated by the Diffie-Hellman Key exchange. Used			
	to derive the session key.			
Diffie-Hellman Private Key	Private Diffie-Hellman component used during Session Key			
	agreement.			
User password	To authenticate users to the product.			
DRNG Seed Key	Seed key used as input into the FIPS 186-2 DRNG.			
DRNG Seed Values	Seed values used as input into the FIPS 186-2 DRNG.			
Server Private Key	Private portion of the key pair used to authenticate the remote			
	server and verify the authenticity of a software image or update			
	during the module integrity test.			

Figure 7: CSPs used by McAfee Endpoint Encryption Manager

Key type	Purpose
Manufacturer Public Key	DSA Key used to authenticate software during power-up self tests
	and software updates.
User Authentication Certificate	CAC/PIV Cards only: Employed in the user identification process
	during logon.
Diffie-Hellman Server Public Key	The Server Public Diffie-Hellman component used during Session
	Key agreement.
Diffie-Hellman Client Public Key	The Client Public Diffie-Hellman component generated internally
	by the module and used during Session Key agreement.

Figure 9 Key information

3.7.1 Key generation

McAfee Endpoint Encryption Manager generates symmetric key material and CSPs (and the Diffie-Hellman public/private key components used in session CSP establishment) using a FIPS 186-2 Appendix 3.1 compliant deterministic random number generator. The only symmetric keys/CSPs generated in this way are the Database Key, User Key, User recovery key and the Session Key.

3.7.2 Key entry and output

The module supports the following key entry:

• Entry of the Diffie-Hellman Server Public Key signed with the Server Private Key

The module supports the following key output:

- Plaintext electronic output of the Diffie-Hellman Client Public Key
- Encrypted electronic output of the User Key
- Obfuscated plaintext manual output of the Machine Recovery Key
- Obfuscated plaintext manual output of the User Recovery Key

Note: The Diffie Hellman key exchange takes place between a Server (the cryptographic module) and a Client machine (e.g. Endpoint Encryption for PC Client). The corresponding keys are referred to as Diffie-Hellman Server keys and Diffie-Hellman Client keys.

3.7.3 Key storage

Key material is stored in the McAfee Endpoint Encryption Manager Object Directory in local GPC storage.

3.7.4 Zeroization of key material

All key material managed by the McAfee Endpoint Encryption Manager has the ability to be zeroized.

In meeting the requirements of IG 7.9 for key zeroization, in order to zeroize all keys and CSPs, the operator should to be uninstall the module and then the hard drive on which it was installed should be reformatted and overwritten at least once. The operator should remain present during this process. Uninstallation will remove any plaintext keys and CSPs from memory and from the hard disk. Reformatting the hard drive will remove any encrypted or public keys from the hard disk. In this way all key material is zeroized. There are no user-accessible plaintext keys or CSPs in the module. Following the zeroization process, all keys and CSPs have been erased and overwritten.

3.7.5 Access to key material

The following matrices (Figures 7 and 8) show the access that an operator has to specific keys or other critical security parameters when performing each of the services relevant to his/her role.

					Key			
Service	MPK	DRNGSK	DHK	UAC	DHSPK	DHCPK	DHSS	SK
Create Installation Set

Access rights

- W Write access
- R Read Access
- E Key Entry
- O Key Output
- Z Zeroize Access

Keys

DBK	Database Key
MEK	Machine Key
UEK	User Key
URK	User Recovery Key
MRK	Machine Recovery Key
MPK	Manufacturer Public Key
UAC	User Authentication Certificate
DRNGSK	DRNG Seed Key
DHK	Diffie-Hellman Private Key
DHSS	Diffie-Hellman Shared Secret

DHSPK	Diffie-Hellman Server Public Key
DHCPK	Diffie-Hellman Client Public Key
SK	Session Key
PW	User password
DRNGSD	DRNG Seed Values
SSK	Server Private Key

Note: If a service requires read or write access, it is the service as realized by module processes that requires access to the keys or CSPs. The operator (either User or Crypto Officer) does not have access to the CSPs themselves. The operator may change keys or use keys, but in all cases other than user or machine recovery, has no plaintext access to key material or CSPs. When carrying out user recovery or machine recovery, a Crypto Officer is required to read recovery keys to a remote user of a client module. Such recovery keys are manually output in obfuscated plaintext.

3.8 Cryptographic Algorithms

McAfee Endpoint Encryption Manager supports the following algorithms:

- FIPS-approved algorithms
 - o AES-256 (CAVP Certificate #1366)
 - DSA (CAVP Certificate #446)
 - o SHA-1 (CAVP Certificate #1247)
 - FIPS 186 Appendix 3.1 DRNG (CAVP Certificate #752).
- Non FIPS-approved algorithms:
 - Diffie-Hellman (key establishment methodology provides 80-112 bits of encryption strength since the module may use 1024 and 2048 bit DH keys)
 - o MD5-based NDRNG (Used to seed the FIPS approved DRNG)

3.9 Self-Tests

McAfee Endpoint Encryption Manager implements both power-up and conditional self tests as required by FIPS 140-2. The following two sections outline the tests that are performed.

3.9.1 Power-up self-tests

The following table, Figure 9, lists the power-up self-tests performed by the module:

SHA-1 known answer test
DSA known answer test
AES-256 known answer test
Software integrity test (DSA Signature verification)
Deterministic Random Number Generator Known Answer Test

Figure 12: Power-up Self-tests

Each of these tests is executed when the computer is turned on and the module first executes. If any of these tests fail, the module will not load. The module must be reset to re-execute these tests.

3.9.2 Conditional self-tests

There are a number of conditional tests that are run by the module. A continuous random number generator test is run every time the module requests a random number from either the FIPS Approved 186-2 DRNG or the MD5-based NDRNG. Failure of this test may result in keys not being generated and an appropriate error message will be given. A software integrity test is also done whenever a component is dynamically loaded into the module. All files are digitally signed and this signature is checked prior to any load operation.

3.10 Design Assurance

McAfee, Inc. employ industry standard best practices in the design, development, production and maintenance of the McAfee Endpoint Encryption product range, including the FIPS 140-2 module.

This includes the use of an industry standard configuration management system that is operated in accordance with the requirements of FIPS 140-2, such that each configuration item that forms part of the module is stored with a label corresponding to the version of the module and that the module and all of its associated documentation can be regenerated from the configuration management system with reference to the relevant version number.

Design documentation for the module is maintained to provide clear and consistent information within the document hierarchy to enable transparent traceability between corresponding areas throughout the document hierarchy, for instance, between elements of this Cryptographic Module Security Policy (CMSP) and the design documentation.

Guidance appropriate to an operator's Role is provided with the module and provides all of the necessary assistance to enable the secure operation of the module by an operator, including the Approved security functions of the module.

3.11 Mitigation of Other Attacks

The module does not mitigate other attacks.

4 FIPS Mode

The following procedures must be followed to operate McAfee Endpoint Encryption Manager cryptographic module in a FIPS Approved mode. For more information please refer to the McAfee Administrators Guide for Endpoint Encryption for PCs:

- 1. The module software must be freshly installed in order to operate in FIPS mode, and not installed as an upgrade to an existing installation.
- 2. When installing the module, accept the default options. However, in the "Optional Components" page, deselect "Endpoint Encryption Web Recovery (Apache/CGI), and deselect all tokens except for "ActivIdentity Certificate Smartcard/USB Key" and "PIV Smart Card (PKI)", that is "ActivIdentity Certificate Smartcard/USB Key" and "PIV Smart Card (PKI)" are the only tokens selected.
- 3. The module software must be operating in "FIPS" mode. This is done by setting the FIPS registry key value from 0 (disabled) to 1 (enabled). The first step is to create a FIPS registry script (see Appendix A for details). Once the file is created, right click on the newly created .reg file and select merge from the drop down menu.
- 4. To verify that the registry has been updated properly the user must install a registry editor and navigate to HKEY_LOCAL_MACHINE\Software\SafeBoot International and verify the value of FipsMode equals 1.
- 5. The McAfee Endpoint Encryption Manager must be configured so that all Crypto Officers have an administration privilege level of 32 and the all Users have an administration privilege level of 1, and that users only have view access to audit data and to objects and their properties and that Users are not allowed to control machines, create installation sets or perform recovery operations.
- 6. Users of the cryptographic modules must use one of the tokens defined in section 3.4.1 to authenticate themselves to the module.
- 7. The PC operating environment must match one of those defined in section 3.3.
- 8. The PC used to run McAfee Endpoint Encryption Manager Client must be built using production grade components.

5 Appendix A – Creating the FIPS enable script

The following needs to be saved to a text file with the extension ".reg" and then merged into the registry as a requirement for installing the module in a FIPS-compliant mode of operation:

REGEDIT4

```
[HKEY_LOCAL_MACHINE\Software\SafeBoot International]
"FipsMode"=dword:00000001
```
