1. Introduction

This document is a non-proprietary FIPS 140-2 Security Policy for the McAfee NGFW Cryptographic Library module. The current version of the module is 2.0. An earlier version of this module has gone through FIPS 140-2 validation under certificate #2031. This document contains a specification of the rules under which the module must operate and describes how this module meets the requirements as specified in the Federal Information Processing Standards Publication (FIPS PUB) 140-2 for a Security Level 1 multi-chip standalone software module.

1.1. Purpose of the Security Policy

There are three major reasons that a security policy is required:

- For FIPS 140-2 validation,
- Allows individuals and organizations to determine whether the cryptographic module, as implemented, satisfies the stated security policy, and
- Describes the capabilities, protection, and access rights provided by the cryptographic module, allowing individuals and organizations to determine whether it will meet their security requirements.

1.2. Target Audience

This document is intended to be part of the package of documents that are submitted for FIPS validation. It is intended for the following people:

- Developers working on the release
- FIPS 140-2 testing lab
- Cryptographic Module Validation Program (CMVP)
- Consumers

2. Cryptographic Module Specification

This document is the non-proprietary security policy for the McAfee NGFW Cryptographic Library and was prepared as part of the requirements to FIPS 140-2, Level 1.

The following section describes the module and how it complies with the FIPS 140-2 standard in each of the required areas.

2.1. Description of Module

The McAfee NGFW Cryptographic Library is a shared library that provides a C-language application programming interface for use by McAfee applications. Assembly language optimizations are used in the cryptographic module implementation.

The files consisting of the logical boundary of the module are the module binary file libqscrypto.so.2 and the checksums.fips file that contains the HMAC-SHA-256 value needed for the module integrity check. The module contains the following cryptographic functionality:

- Pseudo random number generation
- Cryptographic hash functions
- Message authentication code functions
- Symmetric key encryption and decryption
- Public key cryptography: key pair generation, digital signature generation and verification
- Key agreement and establishment
- Key wrapping

The following table shows the overview of the security level for each of the eleven sections of the validation.

Security Component	Security Level
Cryptographic Module Specification	1
Cryptographic Module Ports and Interfaces	1
Roles, Services and Authentication	1
Finite State Model	1
Physical Security	1
Operational Environment	1
Cryptographic Key Management	1
EMI/EMC	1
Self Tests	1
Design Assurance	3
Mitigation of Other Attacks	N/A

Table 1: Security Levels

The module has been tested on the following platforms:

© 2015 McAfee, Inc./atsec information security. This document can be reproduced and distributed only whole and intact, including this copyright notice.

Manufacturer	Model	O/S & Ver.	AES-NI
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Atom Processor D525 (single-user mode)	Not Supported
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Xeon E5-2680 (single-user mode)	With AES-NI
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Xeon E5-2680 (single-user mode)	With and Without AES- NI
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Xeon Processor E5-2660 (single-user mode)	With and Without AES- NI
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Xeon Processor E5-1650v2 (single-user mode)	With AES-NI
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Core i3-2115c (single-user mode)	With AES-NI
McAfee		Debian GNU/Linux 6.0-based distribution running on Intel Celeron Processor 725c (single-user mode)	With AES-NI

Table 2: Tested Platforms

2.2. Description of Approved Mode

The cryptographic module supports only a FIPS 140-2 approved mode. The calling application can invoke ssh_crypto_get_certification_mode() to check the status of the module. It returns SH_CRYPTO_CERTIFICATION_FIPS_140_2 to indicate that the module is indeed in the FIPS-APPROVED mode.

The module provides the following algorithms and services:

- AES: key wrapping, encryption and decryption; ECB, CBC, OFB, CFB128 and GCM modes
- Triple-DES: encryption and decryption; ECB, CBC, OFB and CFB64 modes
- DSA: key generation, digital signatures, and verification
- RSA: key generation, digital signatures, and verification
- ECDSA: key generation, digital signature, and verification
- DRBG: random number generation
- SHS: hashing
- HMAC: message authentication code

In addition, the module provides the following key establishment methods:

- Diffie-Hellman key agreement as key establishment method
- EC Diffie-Hellman: key agreement as key establishment method

2.3. Cryptographic Module Boundary

2.3.1. Software Block Diagram

The logical boundary of the module is the Cryptographic Library itself, which is indicated by the "Cryptographic Boundary" rectangle as illustrated in the diagram below.

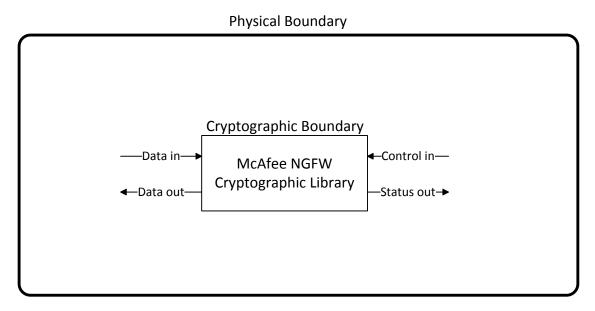

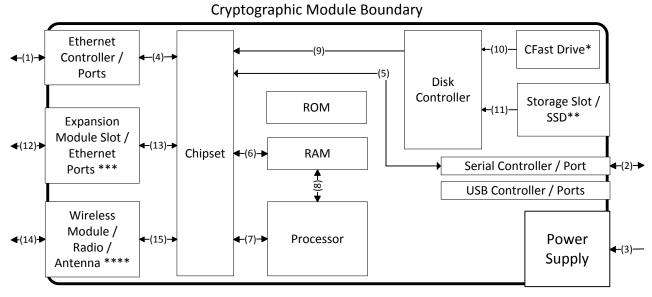

Figure 1: Software Block Diagram

2.3.2. Hardware Block Diagram

The physical boundary of the module is the enclosure of the appliance that the module is running on. The module was tested on seven separate appliances, all of which are general purpose computers. The hardware block diagram below depicts all test appliances and their internal components and ports (processor, SSD, USB, Ethernet, etc.).

- 1, 2, 4, 5, 6, 7, 8, 12, 13, 14 and 15: Data in, data out, control in, status out
- 3: Power in
- 9, 10 and 11: Control in
- *) MIL-320, 1035, 1065
- **) 1402, 3202, 3206, 5206
- ***) 1035, 1065, 1402, 3202, 3206, 5206
- ****) MIL-320 only

Figure 2: Hardware Block Diagram

3. Cryptographic Module Ports and Interfaces

FIPS Interface	Physical Ports	Logical Ports
Data Input	Ethernet ports, serial port, wireless radio	API input parameters
Data Output	Ethernet ports, serial port, wireless radio	API output parameters
Control Input	Ethernet ports, serial port, wireless radio	API function calls
Status Output	Ethernet ports, serial port, wireless radio	API return values
Power Input	PC power supply port	N/A

Table 3: Ports and Interfaces

4. Roles, Services, and Authentication

4.1. Roles

The module implements both a User and a Crypto Officer role. The module does not allow concurrent operators.

The User and Crypto Officer roles are implicitly assumed by the entity accessing services implemented by the module. No further authentication is required. The Crypto Officer can install and initialize the module.

4.2. Services

Table 4: Services

4.3. Operator Authentication

There is no operator authentication; assumption of role is implicit by action.

4.4. Mechanism and Strength of Authentication

No authentication is required at Security Level 1; authentication is implicit by assumption of the role.

5. Finite State Machine

The following diagram represents the states and transitions of the cryptographic module.

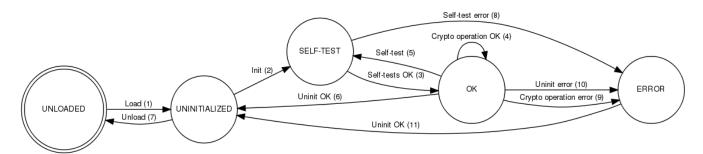

Figure 3: Cryptographic Module Finite State Machine

The state model contains the following states:

- UNLOADED: The start state of the cryptographic module is UNLOADED. The module is in this state until
 the shared library is loaded and linked to the application. Cryptographic operations are not available while in
 this state.
- UNINITIALIZED: The module is in the UNINITIALIZED state after it has been loaded but not yet initialized, or it has been successfully uninitialized. Cryptographic operations are not available while in this state.
- SELF-TEST: The module performs power-up self-tests during initialization or on-demand. Cryptographic operations are not available while in this state.
- OK: The module enters the FIPS mode in the "OK" state after successfully passing the power-up self-tests.
 The cryptographic services are available in this state.
- ERROR: The module enters this state after a self-test, a cryptographic operation or uninitialization has failed.
 An error indicator is output by the module.

The state transitions are as follows:

- 1. The shared library is loaded and linked dynamically to the application.
- 2. The cryptographic module is initialized using the ssh_crypto_library_initialize function. The function is called automatically when the shared library is loaded.
- 3. The self-tests succeed.
- 4. A cryptographic operation is performed successfully.
- 5. On-demand self-tests are performed using the ssh_crypto_library_self_tests function.
- The cryptographic module is uninitialized using the ssh_crypto_library_uninitialize function.
- 7. The shared library is unloaded.
- 8. Power-up self-tests fail.
- 9. A conditional test fails during a cryptographic operation.
- 10. The module uninitialization fails because cryptographic objects are still referenced.
- 11. Cryptographic objects are no longer in use and the module uninitialization succeeds. This transition also occurs automatically when the power-up self-tests fail during the module initialization.

6. Physical Security

The cryptographic module is tested on the McAfee MIL-320, 5206, 3206, 3202, 1402, 1065 and 1035 appliances that consist of production-grade components with standard passivation and a production-grade enclosure.

7. Operational Environment

This module will operate in a modifiable operational environment per the FIPS 140-2 definition. The module operates on the McAfee NGFW Debian GNU/Linux based hardened operating system that is set in the FIPS compatible mode of operation. Login to the operating system is disabled and only the preinstalled McAfee application is running on the system. Therefore the operational environment is considered non-modifiable. The application that uses the cryptographic module is also the single user of the module.

8. Cryptographic Key Management

Keys are established externally. CSPs can be accessed only using the API. The operating system protects the memory and the address space of the process from unauthorized access.

Name	Auth Role	Generation	Туре	Output	Storage	Zeroization
HMAC key for module integrity check	User, CO	Manufacturer	128 bits N/A In module binary		Zeroization is not required per FIPS IG 7.4	
AES symmetric keys	User	External, electronic entry	Symmetric key	N/A	Plaintext in memory	API call, power off
Triple-DES symmetric keys	User	External, electronic entry	Symmetric key	N/A	Plaintext in memory	API call, power off
DSA private key	User	DSA key generation using DRBG, externally using DSA key entry	Private key	Encrypted, plaintext	Plaintext in memory	API call, power off
RSA private key	User	RSA key generation using DRBG, externally using RSA key entry	Private key	Encrypted, plaintext	Plaintext in memory	API call, power off
ECDSA private key	User	ECDSA key generation using DRBG, externally using ECDSA key entry	Private key	Encrypted, plaintext	Plaintext in memory	API call, power off
HMAC key	User	External, electronic entry	HMAC key	N/A	Plaintext in memory	API call, power off
DRBG entropy input	User	External, electronic entry	Entropy input	N/A	Plaintext in memory	API call, power off
DRBG seed	User	/dev/random	Seed	N/A	Plaintext in memory	API call, power off
Diffie- Hellman secret	User	DSA key generation using DRBG	Private key	N/A	Plaintext in memory	API call, power off
Diffie- Hellman	User	Generated through Diffie-Hellman	Symmetric	Plaintext	Plaintext in	API call, power off

^{© 2015} McAfee, Inc./atsec information security. This document can be reproduced and distributed only whole and intact, including this copyright notice.

Name	Auth Role	Generation	Туре	Output	Storage	Zeroization
shared secret		protocol	key		memory	
EC Diffie- Hellman secret	User	ECDSA key generation using DRBG,	Private key	N/A	Plaintext in memory	API call, power off
EC Diffie- Hellman shared secret	User	Generated through Diffie-Hellman protocol	Symmetric key	Plaintext	Plaintext in memory	API call, power off

Table 5: Key Management

8.1. Random Number Generation

The cryptographic module implements an AES block cipher based DRBG with derivation function according to SP 800-90A. The module obtains the seed and the entropy input string by default from /dev/random. The entropy source can be changed by setting the new source either in the /etc/qscrypto.entropysource file or in the LIBQSCRYPTO_ENTROPY_SOURCE environment variable. The seed and the entropy input string are both 256 bytes long. Their security strength is 256 bits, i.e., 1 bit per byte is assumed. In the operational environment, /dev/random is used as the entropy source. The Linux kernel has been patched to contain the CPU Jitter Random Number Generator [19].

8.2. Key/CSP Generation

DSA key pairs are generated using random bits from DRBG according to FIPS 186-4 Appendix B.1.1.

RSA key pairs are generated using probable primes with conditions using auxiliary probable primes and random bits from the DRBG according to FIPS 186-4 Appendix B.3.6.

ECDSA key pairs are generated using extra random bits from the DRBG according to FIPS 186-4 Appendix B.4.1.

Diffie-Hellman and EC Diffie-Hellman secrets and public values are generated using random bits from the DRBG.

8.3. Key/CSP Establishment

The cryptographic module supports Diffie-Hellman primitives for key agreement using ephemeral keys:

- FFC DH dhEphem, C(2, 0, FFC DH) using 2048-bit group
- ECC CDH Ephemeral Unified Model, C(2, 0, ECC CDH) using p-224, p-256, p-384, and p-521 curves

CAVEAT 1: Diffie-Hellman key agreement; key establishment methodology provides 112 bits of encryption strength;

CAVEAT 2: EC Diffie-Hellman key agreement; key establishment methodology provides between 112 and 256 bits of encryption strength.

The cryptographic module also supports the AES key wrapping algorithm as key transport method to wrap the private keys for imports/exports. The AES algorithm is FIPS 140-2-approved and its implementation in the module is certified by CAVP. The key size for AES key wrap can be 128, 192 or 256 bits depending on the key that is provided by the calling application.

© 2015 McAfee, Inc./atsec information security. This document can be reproduced and distributed only whole and intact, including this copyright notice.

CAVEAT 3: AES key wrapping; key establishment methodology provides between 128 and 256 bits of encryption strength.

8.4. Key Entry and Output

The cryptographic module supports electronic entry of symmetric keys and HMAC keys. The application using the cryptographic module can import secret keys to the module in plaintext within the physical boundary. In addition, private keys can be imported encrypted using AES key wrapping.

Private keys can be exported in plaintext to the application using the module within the physical boundary. In addition, private keys can be exported encrypted using AES key wrapping.

There is no output of intermediate key generation values from the module at any point in time. The module does not support manual entry of keys.

8.5. Key Storage

The keys and CSPs are stored in plaintext in memory. The module does not provide persistent storage of keys.

8.6. Zeroization Procedure

The stored keys and CSPs are zeroized when the application calls the appropriate API function: ssh_cipher_free, ssh_mac_free, ssh_private_key_free, ssh_pk_group_free and ssh_crypto_library_uninitialize. Intermediate key material is zeroized automatically by the module when no longer needed. All keys and CSPs can be zeroized by powering off the module and performing a system restore operation by the operational environment.

9. Self-Tests

9.1. Power-Up Tests

The power-up self-tests are executed automatically when the cryptographic module is loaded. The ssh_crypto_library_initialize() function returns 0 (SSH_CRYPTO_OK) when the power-up self-tests are successfully completed.

If the power-up self-tests fail, the cryptographic module outputs an error message and enters an error state. No further operations are allowed when the module is in an error state. The cryptographic module causes the process termination with a non-zero exit status when the power-up self-tests have failed. The computer will need to be restarted in order for the cryptographic module to enter to an operational state.

Self-tests are performed on-demand when the user calls the ssh_crypto_library_self_tests() function.

Algorithm	Test	
AES	Known Answer Test (KAT), encryption and decryption are tested separately	
Triple-DES	KAT, encryption and decryption are tested separately	
DSA	Pair-wise consistency test (PCT) for DSA key pair generation	
RSA	KAT for signature generation and verification tested separately, PCT for RSA key pair generation	
ECDSA	KAT for signature generation, PCT for ECDSA key pair generation	
SHS	KAT for SHA-1, SHA-256 and SHA-512	
HMAC	KAT for HMAC-SHA-1, HMAC-SHA-256 and HMAC-SHA-512	
DRBG	KAT	
Diffie-Hellman	KAT, PCT	
EC Diffie-Hellman	KAT, PCT	

Table 7: Power-Up Tests

The following are the error messages related to self-test failure:

Reason For Failure	Error Message
Failure of AES/Triple-DES KAT	Cipher algorithm test failed during self-test
Failure of RSA/DSA/Diffie- Hellman KAT or PCT	Public key algorithm test failed during self-test
Failure of ECDSA/EC-Diffie- Hellman KAT or PCT	Unknown error code (exit code 160)
Failure of SHS KAT	Hash algorithm test failed during self-test
Failure of HMAC KAT	Mac algorithm test failed during self-test
Failure of integrity test	The checksum of the library is incorrect. Integrity has been compromised

Table 8: Error Messages Related to Self-Test Failure

^{© 2015} McAfee, Inc./atsec information security. This document can be reproduced and distributed only whole and intact, including this copyright notice.

It is the applications responsibility to reboot the appliance to recover the module from the error state. The library will not cause the rebooting of the appliance.

9.2. Integrity Check

The cryptographic module uses the HMAC-SHA-256 message authentication code of the module binary for the integrity tests. The module reads the module binary file, computes the HMAC-SHA-256 MAC of the file content and compares it to the known correct MAC that is input to the module when it is loaded.

9.3. Conditional Tests

Algorithm	Test
DSA	Pair-wise consistency test
RSA	Pair-wise consistency test
ECDSA	Pair-wise consistency test
DRBG	Continuous test

Table 9: Conditional Tests

The following are the error messages related to conditional test failure:

Reason For Failure	Error Message
Failure of DSA pair-wise	One of the following (%d is error code):
consistency test	Private key consistency test failed: %d Public key consistency test failed: %d DH group consistency test failed: %d
	and
	Cryptographic Library error occurred (1)
Failure of RSA pair-wise consistency test	One of the following (%d is error code): Private key consistency test failed: %d Public key consistency test failed: %d and
	Cryptographic Library error occurred (1)
Failure of ECDSA pair-wise	One of the following (%d is error code):
consistency test	Private key consistency test failed: %d Public key consistency test failed: %d DH group consistency test failed: %d
	and
	Cryptographic Library error occurred (1)
Failure of DRBG continuous test	Continuous DRBG test failed Cryptographic Library error occurred (0)

Table 10: Error Messages Related to Conditional Test Failure

^{© 2015} McAfee, Inc./atsec information security. This document can be reproduced and distributed only whole and intact, including this copyright notice.

10. Design Assurance

10.1. Configuration Management

Git and Lotus Notes are used for configuration management of the cryptographic module.

10.2. Delivery and Operation

The cryptographic module is never released as source code. It is delivered as part of the McAfee NGFW software (formerly Stonesoft Security Engine). The FIPS 140-2-compatible McAfee NGFW software image is downloaded from the McAfee website. The McAfee NGFW software is also preinstalled on McAfee NGFW appliances (see Table 2: Tested Platforms). Product information for the appliances is available at the McAfee website: http://www.mcafee.com/us/products/next-generation-firewall.aspx

10.2.1. Downloading a FIPS 140-2-compatible engine version

A FIPS 140-2-compatible version of the McAfee NGFW software is downloaded as follows:

- 1. Go to the McAfee NGFW Downloads page at https://my.stonesoft.com/download.do.
- 2. Enter the Proof-of-License (POL) or Proof-of-Serial (POS) code in the License Identification field and click **Submit**.
- 3. Click McAfee NGFW downloads. The McAfee NGFW Downloads page opens.
- 4. Download the .zip installation file.
- 5. Verify the SHA checksum. The correct checksum is shown on the download page.

10.3. Cryptographic Officer Guidance

10.3.1. Installation

The cryptographic module is delivered as part of the McAfee NGFW software. To run the cryptographic module on a McAfee NGFW appliance, the NGFW software is set to a FIPS 140-2-compatible operating mode.

10.3.1.1 Upgrading appliances to the FIPS 140-2-compatible engine version

McAfee NGFW appliances are delivered with the most recent engine software preinstalled. The engine software must be upgraded to the FIPS 140-2-compatible engine version before entering FIPS-compatible operating mode. This is necessary even if the same version was installed previously, because the file system checksum is stored during the upgrade process.

To upgrade to the FIPS-compatible engine version:

- Save the FIPS 140-2-compatible engine upgrade zip file in the root directory of a USB memory stick. Note The engine upgrade zip file must be in the root directory of the media.
- 2. Boot up the appliance. The Engine Configuration Wizard starts.
- 3. Select **Upgrade**. The Select Source Media dialog opens.
- 4. Select **USB Memory**. The upgrade starts.
- 5. Select **OK**. The engine reboots and the Engine Configuration Wizard starts with the engine image verification dialog shown. Select **Calculate**. The file system checksum is calculated and displayed below the checksum from the engine image zip file.
- 6. Verify that the calculated checksum is identical to the checksum from the zip file.

© 2015 McAfee, Inc./atsec information security. This document can be reproduced and distributed only whole and intact, including this copyright notice.

- 7. Select **OK**. The engine reboots.
- 8. Check the engine version to make sure that the certified version is loaded.

Continue as instructed in Configuring the engine, below.

10.3.1.2 Configuring the engine

To configure the engine:

- 1. Start the Engine Configuration Wizard as instructed in the **Configuring the Engine in the Engine Configuration Wizard** section of the *McAfee NGFW Installation Guide*.
- Configure the Operating System settings as instructed in the Configuring the Operating System Settings section of the McAfee NGFW Installation Guide. Select Restricted FIPS-compatible operating mode. The SSH daemon and root password options are automatically disabled in the Engine Configuration Wizard.
- 3. Configure the network interfaces according to your environment as instructed in the **Configuring the Network Interfaces** section of the *McAfee NGFW Installation Guide*.
- 4. Contact the Management Server as instructed in the **Contacting the Management Server** section of the *McAfee NGFW Installation Guide*. Enter node IP address manually is selected by default and other IP address options are disabled when FIPS-compatible operating mode is enabled.

The engine restarts.

10.3.1.3 Verifying activation of FIPS 140-2-compatible operating mode

Restricted FIPS-compatible operating mode must be enabled during the initial configuration of the appliance. The following steps describe how to verify that FIPS 140-2-compatible operating mode has been activated.

To verify activation of FIPS 140-2-compatible operating mode:

1. Verify that the following messages are displayed on the console when the engine restarts:

```
FIPS: rootfs integrity check OK
```

(displayed after the root file system integrity test has been executed successfully)

```
FIPS power-up tests succeeded
```

(displayed after the FIPS 140-2 power-up tests have been executed successfully)

2. Continue as instructed in the **After Successful Management Server Contact** section of the *McAfee NGFW Installation Guide*.

Note – If the engine does not enter the FIPS 140-2-compatible operating mode even though it is configured to do so, or if the power-up tests fail (a power-up test error message is displayed or the success message is not displayed), the appliance must be reset to factory settings and reinstalled as instructed in **Recovering from a FIPS 140-2 self-test failure.**

10.3.1.4 Resetting the appliance to factory settings

Resetting the appliance to factory settings is not part of the normal installation procedure. There is no need to reset the appliance to factory settings before starting to use it for the first time. These instructions can be used to reset the appliance to factory settings when necessary, such as when initial configuration has been completed without enabling the Restricted FIPS 140-2-compatible operating mode, during use, or when the appliance is being removed from use.

To reset the appliance to factory settings:

- Reboot the appliance and select System restore options from the boot menu. McAfee NGFW System Restore starts.
- 2. Enter 2 for Advanced data removal options.
- 3. Enter one of the following options:
 - 1 for 1 pass overwrite
 - 8 for a Custom number of overwrite passes

If you selected **Custom**, enter the number of overwrite passes. A larger number of overwrites is more secure, but it may take a considerable amount of time depending on the appliance storage capacity.

10.3.1.5 Recovering from a FIPS 140-2 self-test failure

If the FIPS 140-2 power-up self-tests fail, or the engine does not enter FIPS 140-2-compatible operating mode, the appliance must be reset to factory settings and reinstalled according to these instructions. Begin by **Resetting the appliance to factory settings**.

To recover from a FIPS 140-2 self-test failure:

- 1. Reset the appliance to factory settings as instructed in **Resetting the appliance to factory settings**.
- 2. Repeat the engine version upgrade as instructed in **Upgrading appliances to the FIPS 140-2-compatible engine version**.
- 3. Configure the firewall engine and enable FIPS 140-2-compatible operating mode as instructed in **Configuring the engine**.
- 4. Verify that FIPS-compatible operating mode is activated as instructed in **Verifying activation of FIPS 140- 2-compatible operating mode**.

10.3.2. Entropy Source

The cryptographic module uses /dev/random as the default entropy source. The entropy source can be changed by setting the new source either in the /etc/qscrypto.entropysource file or in the LIBQSCRYPTO_ENTROPY_SOURCE environment variable.

/dev/random is always used as the entropy source for the cryptographic module when the McAfee NGFW software is in FIPS-compatible operating mode.

10.3.3. Initialization

The cryptographic module is initialized using the ssh_crypto_library_initialize() function before any cryptographic functionality is available. In order for the integrity check to succeed, the known HMAC-SHA-256 MAC needs to be available either in:

/etc/checksums.fips file

or

LIBQSCRYPTO CHECKSUM environment variable

The /etc/checksums.fips file is provided with the McAfee NGFW software.

10.4. User Guidance

10.4.1. AES GCM

In case the module's power is lost and then restored, the key used for the AES GCM encryption/decryption shall be re-distributed.

10.4.2. Zeroization

When a cryptographic key is no longer used, the key must be zeroized and freed using the ssh_cipher_free, ssh_mac_free and ssh_private_key_free functions for symmetric key encryption/decryption, message authentication and public key cryptography, respectively.

10.4.3. Key Export

Private keys must not be exported unencrypted outside the physical module boundary from the application using the cryptographic module.

11. Mitigation of Other Attacks

No other attacks are mitigated.
