1. Introduction

This is a non-proprietary FIPS 140-2 Security Policy for the Senetas Corporation Ltd. and SafeNet Inc. CN Series Ethernet Encryption devices comprising of the CN4010 and CN6010 (version 2.6.1) cryptographic models. This Security Policy specifies the security rules under which the module operates to meet the FIPS 140-2 Level 3 requirements.

FIPS 140-2 (Federal Information Processing Standards Publication 140-2), *Security Requirements for Cryptographic Modules*, specifies the security requirements for a cryptographic module utilized within a security system protecting sensitive but unclassified information. Based on four security levels for cryptographic modules this standard identifies requirements in eleven sections. For more information about the NIST/CSE Cryptographic Module Validation Program (CMVP) and the FIPS 140-2 standard, visit www.nist.gov/cmvp.

This Security Policy, using the terminology contained in the FIPS 140-2 specification, describes how the CN4010 1G Ethernet Encryptor and the CN6010 1G Ethernet Encryptor models comply with the eleven sections of the standard. In this document, the CN4010 and CN6010 Encryptors are collectively referred to as the “CN Series” and individually as “the module” or “the encryptor”.

This Security Policy contains only non-proprietary information. Any other documentation associated with FIPS 140-2 conformance testing and validation is proprietary and confidential to Senetas Corporation Ltd. & SafeNet Inc. and is releasable only under appropriate non-disclosure agreements. For more information describing the CN Series systems, visit <http://www.senetas.com>.

1.3 Acronyms and Abbreviations

AES	Advanced Encryption Standard
ATM	Asynchronous Transfer Mode
CA	Certification Authority
CBC	Cipher Block Chaining
CFB	Cipher Feedback
CM	Senetas Encryptor Remote Management Application Software
CI	Connection Identifier (used interchangeably with Tunnel)
CLI	Command Line Interface
CMP	Certificate Management Protocol
CMVP	Cryptographic Module Validation Program
CSE	Communications Security Establishment
CSP	Critical Security Parameter
CTR	Counter Mode
DEK	Data Encrypting Key(s)
DES	Data Encryption Standard
DRBG	Deterministic Random Bit Generator
ECDH	Elliptic Curve Diffie-Hellman
ECDSA	Elliptic Curve Digital Signature Algorithm
EDC	Error Detection Code
EMC	Electromagnetic Compatibility
EMI	Electromagnetic Interference
FC	Fibre Channel
FCC	Federal Communication Commission
FIPS	Federal Information Processing Standard
Gbps	Gigabits per second
GCM	Galois Counter Mode
HMAC	Keyed-Hash Message Authentication Code
IGMP	Internet Group Management Protocol

IP	Internet Protocol
IV	Initialization Vector
KAT	Known Answer Test
KEK	Key Encrypting Key(s)
LED	Light Emitting Diode
MAC	Media Access Control (Ethernet source/destination address)
Mbps	Megabits per second
MLD	Multicast Listener Protocol
NC	Network Certificate
NIST	National Institute of Standards and Technology
NTU	Network Termination Unit
NVLAP	National Voluntary Laboratory Accreditation Program
OCSP	Online Certificate Status Protocol
PKCS	Public Key Cryptography Standards
PKI	Public Key Infrastructure
PUB	Publication
RAM	Random Access Memory
RFC	Request for Comment
ROM	Read Only Memory
RNG	Random Number Generator
RSA	Rivest Shamir and Adleman Public Key Algorithm
RTC	Real Time Clock
SAN	Storage Area Network
SFP	Small Form-factor Pluggable (transceiver)
SMC	SafeNet's Security Management Center
SMK	System Master Key
SHA	Secure Hash Algorithm
TRANSEC	TRANsmission SECurity
XFP	10 Gigabit Small Form Factor Pluggable (transceiver)
X.509	Digital Certificate Standard RFC 2459

2. Product Description

CN Series Ethernet Encryptors are multiple-chip standalone cryptographic modules consisting of production-grade components contained, in accordance with FIPS 140-2 Level 3, in a physically protected enclosure. Excluding the pluggable SFP transceivers, dual redundant power supplies and replaceable fan tray module of the CN6010, the module's outer steel casing defines the cryptographic boundary. The CN4010's cryptographic boundary extends to the outer aluminium casing and excludes the "AC to DC" plug-pack adapter. Each cryptographic module is completely enclosed in a metal case which is protected from tampering by internal tamper protection circuitry and external tamper response seals. Any attempt to remove the cover automatically erases all sensitive information stored internally in the cryptographic module.

The module meets the overall requirements applicable to Level 3 security for FIPS 140-2.

2.1 Module Identification

CN Series Ethernet Encryptors, with firmware version 2.6.1, provide data privacy and access control services for Ethernet networks. See model details summarized in Table 2.

Data privacy is provided by FIPS approved AES and Triple-DES algorithms. The complete list of approved module algorithms is included in the *Approved Security Function* table.

Table 2 CN Series Ethernet models: Hardware/Firmware Versions

Hardware Versions	Power	Interface / Protocol (Cryptographic Module)	Firmware Version
A4010B [O] A4010B [Y]	DC	1G Ethernet This model derives its power from an “AC to DC” plug-pack adapter which is considered to be outside the cryptographic boundary.	2.6.1
A6010B [O] A6010B [Y]	AC	1G Ethernet	2.6.1
A6011B [O] A6011B [Y]	DC	This model supports pluggable SFP transceivers, dual power supplies and removable fan tray which are considered to be outside the cryptographic boundary.	
A6012B [O] A6012B [Y]	AC/DC		

Table Notes:

[O]¹ denotes Senetas Corp. Ltd. sole branded version

[Y]¹ denotes Senetas Corp. Ltd. & SafeNet Inc. co-branded version

SafeNet logo co-branding added to fascia

Figure 1 – SafeNet co-branding

¹. [O] and [Y] variants are identical except for the addition of the SafeNet logo on the front fascia.

2.2 Operational Overview

2.2.1 General

CN Series Ethernet Encryptors operate in point-to-point and point-to-multipoint network topologies and at data rates ranging from 10Mb/s to 1Gb/s.

Encryptors are typically installed between an operator's private network equipment and public network connection and are used to secure data travelling over either fibre optic or CAT5/6 cables.

Securing a data link that connects two remote office sites is a common installation application.

Figure 2 provides an operational overview of two CN6010 encryptors positioned in the network.

Figure 2 – CN6010 Operational Overview

Devices establish one or more encrypted data paths referred to as `connections`. The term refers to a connection that has been securely established and is processing data according to a defined encryption policy. Each `connection` has a `connection identifier` (CI) and associated atm foruCI mode that defines how data is processed for each policy. Connections are interchangeably referred to as `tunnels`.

CN Series Ethernet Encryptors support CI Modes of 'Secure', 'Discard' and 'Bypass'. These CI Modes can be applied to all data carried on a connection or to a selected subset or grouping which can be user configured in accordance the specific protocol being carried on the network connection. A typical example in the case of an Ethernet network would be to make policy decisions based upon an Ethernet packet's VLAN ID.

The default CI Mode negotiated between a pair of connected encryptors is `Discard`. In this mode user data is not transmitted to the public network.

In order to enter `Secure` mode and pass information securely, each encryptor must be `Certified` by the same trusted body and exchange a secret `Session Key` (DEK) using the RSA key exchange process (as specified in the ATM Forum's ATM Security Specification version 1.1). Alternatively, ECDSA/ECDH utilises ephemeral key agreement for the purpose of establishing DEKs in accordance with NIST SP800-56A. If the session key exchange is successful this results in a separate secure session per connection, without the need for secret session keys (DEKs) to be displayed or manually transported and installed.

Figure 3. illustrates the conceptual data flow through a CN Series Ethernet Encryptors.

1. A data packet arrives at the encryptor's interface ports. When operating in Line mode data packets are processed according to a single CI policy, otherwise,
2. The encryptor looks up the appropriate packet header field, e.g. MAC address or VLAN ID and determines whether the field has been associated with an existing CI,
3. If a match is found, the encryptor will process the data packet according to the policy setting for that CI and send the data out the opposite port. If a match cannot be found, the data packet is processed according to the default policy setting.

Figure 3 - Data Flow through the Encryptor

2.2.2 Encryptor deployment

Figure 4 illustrates a point-to-point (or link) configuration in which each module connects with a single far end module and encrypts the entire bit stream. If a location maintains secure connections with multiple remote facilities, it will need a separate pair of encryptor's for each physical connection (link).

Figure 4 - Link Configuration

Figure 5 illustrates a meshed network configuration. Ethernet models will generally operate in this configuration. Each CN Series Ethernet Encryptor is able to maintain simultaneous secured connections with many far end encryptors.

Figure 5 - Meshed Configuration

2.2.3 Encryptor management

Encryptors can be centrally controlled or managed across local and remote stations using the CM or SMC remote management application. Encryptors support both *in-band* and *out-of-band* SNMPv3 management. *In-band* management interleaves management messages with user data on the encryptor's network interface port whilst *out-of-band* management uses the dedicated front panel Ethernet port. A Command Line Interface (CLI) is also available via the console RS-232 port.

FIPS-Approved mode of operation enforces the use of SNMPv3 privacy and authentication. Management messages are encrypted using AES-128. Non-Approved mode allows message privacy to be disabled in order to interwork with 3rd party legacy management applications.

2.2.4 Ethernet implementation

Basic operation

The Ethernet encryptor provides layer 2 security services by encrypting the contents of data frames across Ethernet networks. The encryptor connects between a local (protected) network and a remote (protected) network across the public (unprotected) network. An encryptor is paired with one or more remote Ethernet encryptors to provide secure data transfer over encrypted connections as shown in Figure 6 below.

Figure 6 – Layer 2 Ethernet connections

The encryptor's Ethernet receiver receives frames on its ingress port; valid frames are classified according to the Ethernet header then processed according to the configured policy.

Allowable policy actions are:

- Encrypt – payload of frame is encrypted according to the defined policy
- Discard – drop the frame, no portion is transmitted
- Bypass – transmit the frame without alteration

CN Series tunnels are encrypted using CAVP validated AES algorithms. The CN4010 and CN6010 1G Ethernet encryptors support AES encryption with a key size of 128 or 256 bits in cipher feedback (CFB), counter (CTR) and Galois Counter (GCM) modes.

Connections between encryptors use a unique key pair with a separate key for each direction. Unicast traffic can be encrypted using AES CFB or CTR modes whereas Multicast/VLAN traffic in a meshed network must use AES CTR mode.

The Ethernet transmitter module calculates and inserts the Frame Check Sequence (FCS) at the end of the frame. The frame is then encoded and transmitted. For details about Unicast and Multicast network topologies supported by the modules see next section.

Unicast operation

Unicast traffic is encrypted using a key pair for each of the established connections.

When operating in line mode there is just one entry in the connection table. When operating in multipoint mode, connection table entries are managed by MAC address or VLAN ID and can be added manually, or if 'Auto discovery' is enabled, they will be automatically added based on the observed traffic. Entries do not age and will remain in the table.

Multicast and broadcast operation

Multicast traffic between encryptors connected in line mode shares the same single key pair that is used by unicast traffic.

Multicast encryption is used to encrypt traffic sent from a host to all members of a multicast group. Unlike unicast encryption (which encrypts traffic from a single sender to a single receiver and uses a unique pair of keys per encrypted connection), multicast encryption within a multipoint network requires a group key management infrastructure to ensure that each encryptor can share a set of encryption keys per multicast MAC address. The group key management scheme which is used for both multicast and VLAN based encryption is responsible for ensuring group keys are maintained across the visible network.

The group key management scheme is designed to be secure, dynamic and robust; with an ability to survive network outages and topology changes automatically. It does not rely on an external key server to distribute group keys as this introduces both a single point of failure and a single point of compromise.

For robustness and security a group key master is automatically elected amongst the visible encryptors within a mesh based on the actual traffic.

If communications problems segment the network, the group key management scheme will automatically maintain/establish new group key managers within each segment.

TRANSEC operation

Traffic Analysis is the process of intercepting and examining messages in order to deduce information from patterns in communication. TRANSEC is TRANsmission SECurity and is used to disguise patterns in network traffic to prevent Traffic Analysis. TRANSEC mode can be optionally enabled between two end points of a point-point rate-limited layer 2 service provider network.

When operating in TRANSEC mode transport frames exit the network port at a constant rate irrespective of the rate at which user data arrives at local port. This ensures that Traffic Analysis, if performed, would generate no useful insight into the user data. The transport frame rate and length are user configurable. AES encryption protects the user data and when operating in GCM encryption mode provides the additional guarantee of data authentication.

TRANSEC mode coupled with AES-256 GCM provides triple layer protection of user data.

Figure 7 – TRANSEC constant rate transport frame assembly

3. Module Ports and Interfaces

The CN Series Ethernet Encryptor ports and interfaces are detailed below.

The CN4010 Branch Office Ethernet Encryptor ports are located on the rear of the module whereas the CN6010 Server Grade Ethernet Encryptor has all ports located on the front of the module.

3.1 CN6010 Encryptor Ports

The CN6010 Ethernet Encryptor data and management ports are located on the encryptor's front panel.

The Local and Network data ports, which provide connectivity between the secure and insecure network respectively, support optical or electrical media in the form of RJ45 electrical or SFP optical physical interfaces.

User access management ports, LCD display, LEDs, Keypad and Erase are also located on the front of the module as presented in Figure 8.

The CN6010 models are depicted below in Figure 8 and Figure 9.

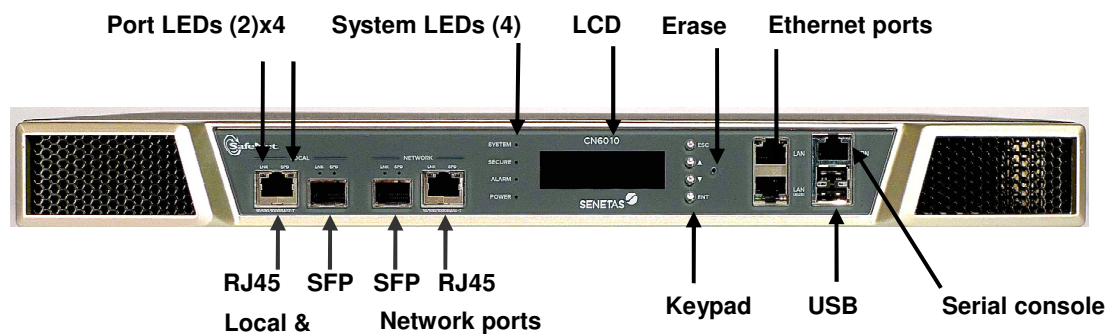

Figure 8 - Front View of the CN6010 [Y] Encryptor

Figure 9 - Front View of the CN6010 [O] Encryptor

The CN6010 1G Ethernet Encryptor supports dual redundant power supplies which are available in two variants, an AC version for typical installs and a DC version for telecoms applications. Any power supply combination i.e. AC/AC, AC/DC or DC/DC is supported. Details of each can be seen in Figure 10.

Figure 10 - Rear View: CN6010 Ethernet Encryptor (pictured with AC & DC supplies installed)

Figure 11 and Figure 12 depict close-up images of the CN6010 module ports and interfaces.

Figure 11 – A6010B [Y] 1G Ethernet port close-up - SFPs installed

Figure 12 – RJ45 Ethernet, Console and USB close-up

3.2 CN4010 Ports

The CN4010 data and management ports are located on the encryptor's rear panel.

The encryptor data ports include a Local Port which connects to the physically secure private network and the Network Port which connects to an unsecured public network.

System status LEDs and emergency Erase are located on the module front panel

The CN4010 models are depicted below in Figure 13 and Figure 14.

Figure 13 - Front View of the CN4010 [Y] Encryptor

Figure 14 - Front View of the CN4010 [O] Encryptor

The CN4010 rear view of the encryption device and is common for the [O] and [Y] variants.

Figure 15 - Rear View of the CN4010 [O] and CN4010 [Y] Encryptors

Table 3 overleaf defines the Physical Ports.

Table 3 CN Series Physical Ports

Port	Location		Purpose
	Front/Rear/na		
	4010	6010	
RJ-45 Ethernet	Rear	Front	Allows secure and authenticated remote management by the selected remote management application.
RJ-45 RS-232 Console	Rear	Front	The Serial Console port connects to a local terminal and provides a simple command line interface (CLI) for initialization prior to authentication and operation in the approved mode. This port also allows administrative access and monitoring of operations. User name and password authentication is required to access this port.
USB	Rear	Front	The USB port provides a mechanism for applying approved and properly signed firmware upgrades to the module.
Keypad (6010 only)	na	Front	Allows entry of commands to display module configuration details.
LCD (6010 only)	na	Front	Displays configuration information in response to commands entered via the navigation keypad.
Power LED	Front	Front	Indicate powered state.
Secure LED	Front/ Rear	Front	Indicate the system secure state
LAN LED	Front	RJ45	Indicate management LAN link status and activity
Local LED	Front	RJ45	Indicate Local Port link status and activity
Network LED	Front	RJ45	Indicate Network link status and activity
Alarm LED	Front/ Rear	Front	Indicate system alarm state
Temperature LED	Front	LCD	Indicate temperature warning alarm
Battery LED	Front	LCD	Indicate internal battery state
Network Port	Rear	Front	The Network Port connects to the public network; access is protected by X.509 certificates. The Network Port is of the same interface type as the Local Port.
Local Port	Rear	Front	The Local Port connects to the private network; access is protected by X.509 certificates. The Local Port is of the same interface type as the Network Port.
Erase	Front	Front	The concealed front panel “Emergency” Erase feature can be activated using a paperclip or similar tool and will immediately delete the System Master Key. The Erase functions irrespective of the powered state of the module.
Power Connectors	Rear	Rear	Provides power to the module AC/DC for CN6010 and DC (via an “AC to DC” plug pack for the CN4010)
Power LEDs	na	Rear	Indicates whether power module is ON or OFF.

3.3 CN Series Interfaces

Table 4 summarizes the FIPS 140-2 defined Logical Interfaces.

Table 4 Logical Interfaces

Interface	Explanation
Data Input	Interface through which data is input to the module.
Data Output	Interface by which data is output from the module.
Control Input	Interface through which commands are input to configure or control the operation of the module.
Status Output	Interface by which status information is output from the module.

The FIPS 140-2 Logical Interfaces map to the Physical Ports as outlined in Table 5.

Table 5 FIPS 140-2 Logical Interface to Physical Port Mapping

FIPS 140-2 Logical Interface	CN Series Interface	Physical Port
Data Input	Private Network Interface	Local Port
	Public Network Interface	Network Port
Data Output	Private Network Interface	Local Port
	Public Network Interface	Network Port
Control Input	Local Console	RJ-45 RS-232 Serial Console
	Keypad & Display	Keypad / LCD
	Remote Management Interface	Management RJ-45 Ethernet Port (LAN)
	Private Network Interface	Local Port
	Public Network Interface	Network Port
Status Output	Local Console	RJ-45 RS-232 Serial Console
	Keypad & Display	Keypad / LCD
	Remote Management Interface	Management RJ-45 Ethernet Port (LAN)
	Private Network Interface	Local Port
	Public Network Interface	Network Port
	LEDs	Front & Rear LEDs
Power	Power Switch	Power Connector

CN Series Ethernet Encryptors support the FIPS 140-2 Logical Interfaces as outlined in Table 6.

Table 6 Interface Support

Logical Interface	Support
<p>Data Input & Data Output</p>	<p>Local Interface:</p> <ul style="list-style-type: none"> Connects to the local (private) network; sends and receives plaintext user data to and from the local network. <p>Network Interface:</p> <ul style="list-style-type: none"> Connects to the public network; sends and receives ciphertext user data, via the public network, to and from a far end cryptographic module. Authenticates with the far end cryptographic module(s); sends and receives authentication data and RSA or ECDSA/ECDH key exchange components to and from a far end module. <p>The module can be set to bypass allowing it to send and receive plaintext user data for selected connections.</p>
<p>Control Input</p>	<p>Control Input is provided by the Local Console, Keypad & Display, and the Remote Management Interface as follows:</p> <ul style="list-style-type: none"> The Keypad supports module initialization prior to authentication and operation in the approved mode. A Crypto Officer sets the IP address for administration by the remote management application; sets the system clock; and loads, in conjunction with the remote management application, the module's certificate. As an alternative to using the Keypad, the Local Console may be used for initialization prior to certification and operation in the approved mode. The Local Console receives control input from a locally connected terminal. Following initialization and authentication, the remote management application can communicate with the module to receive out-of-band control input. <p>When configured for in-band management, the Private and Public Network Interfaces may also receive control input. In this mode, the remote management application sends control input by way of the Local or Network Port rather than the RJ-45 Ethernet.</p>
<p>Status Output</p>	<p>Status output is provided by the Keypad & Display, LEDs, Local Console and the Remote Management Interface as follows:</p> <ul style="list-style-type: none"> The Display presents the Crypto Officer with the command data being entered via the Keypad. It also indicates the state of the X.509 certificates. The System LEDs indicate the system and tunnel state as well a combined alarm status covering network and local ports. The Port LEDs indicate the state of the local and network interfaces and the presence of network traffic. As an alternative to using the Keypad & Display, the Local Console may be used for initialization prior to certification and operation in the approved mode. The Local Console may also be used for monitoring some operations; status output is sent to a locally connected terminal. Following initialization and authentication, the module sends out-of-band status output to the remote management application.

Logical Interface	Support
	When configured for in-band management, the Private and Public Network Interfaces may also send status output. In this mode, the module status output is sent to the remote management application by way of the Local or Network Port rather than the RJ-45 Ethernet Port.

The encryptor does permit logically distinct categories of information to share the Local and Network Ports. For example, when the module is configured to allow in-band management traffic, the control/status information (key exchange or management commands) and user data enter and exit the module via the Network Interface. The module separates these two logically distinct categories of information by employing a unique vendor specific Ethertype to carry in-band management traffic.

4. Administrative Roles, Services and Authentication

The cryptographic module supports four administrative privilege levels: Administrator, Supervisor, Operator and Upgrader. The Administrator role is highest (most unrestricted) privilege level and is authorized to access all module services. FIPS140-2 defines two operator classes, the Crypto Officer, who is granted access to management functions and the User who obtains cryptographic services of the module. Crypto Officers would assume the role of either an Administrator or Supervisor whilst Users can assume the role of an Operator or Upgrader.

The supported roles are summarized in Table 7.

Table 7 Roles

Operator Class	Role
Crypto Officer	Administrator: Provides cryptographic initialization and management functions. Crypto Officer functions are available via the CM or SMC remote management application. Limited functions are also available via the Console interface.
	Supervisor: Provides limited operational management functions. Functions are available via the remote management application. Limited functions are also available via the Console interface.
	Services for the CO are accessible directly via the Local Console CLI or remotely via the Remote Management Interface and the remote management application.
User	Restricted to read-only access to module configuration data.
	Operator: The Operator role is intended to provide sufficient restricted module access for an IT professional to monitor and ensure the network infrastructure to which the encryptor is connected is intact and operational. Services for the Operator are accessible directly via the Local Console CLI or remotely via the Remote Management Interface and the remote management application.
	Upgrader: The Upgrader Role is limited to applying field upgrades to the module firmware. Additional access is restricted to read-only access to module configuration data.
	Services for the Upgrader are accessible directly via the Local Console CLI or remotely via the remote management application.

Roles cannot be changed while authenticated to the module; however, the module permits multiple concurrent operators. While only one operator may connect to the Local Console at a time, multiple concurrent remote sessions are permitted. Remote management is not session oriented; thus, multiple operators may be issuing commands with each command processed individually as it is received by the module. In a meshed network the system architecture supports simultaneous interactions with many far end modules; the multiple users (remote modules) all sending data to the data input port. The module's access control rules, system timing, and internal controls maintain separation of the multiple concurrent operators.

The module does not support a maintenance role. Since there are no field services requiring removal of the cover, physical maintenance is performed at the factory.

Note: A Crypto Officer should zeroize the module before it is returned to the factory. The module can be zeroized using several methods. When the module is powered on, the module can be zeroized by command or by performing the Erase key press sequence defined in the user manual. An immediate erase can be achieved, powered or un-powered, by depressing the concealed front panel Erase button, accessed using a "paperclip" or other suitable tool. Refer to Figure 8 for location.

4.1 Identification and Authentication

The module employs Identity-Based Authentication. Four operator privilege levels have been defined for use, Administrator, Supervisor, Operator and Upgrader with access rights as indicated in Table 8. Restricted Administrator privileges are available until the module is “Activated”. Activation ensures that the default Administrator password is changed and allows additional user accounts to be created. A user with Administrator privilege can further restrict the available privilege levels to Administrator and Operator by selecting “Simplified” user model from the CLI.

Up to 30 user accounts with unique names and passwords may be defined for authorised operators (Administrators, Supervisors Operators and Upgraders) of the module. Users with Administrator privilege can add, delete and edit user accounts. Operators using the Local Console enter their name and password to authenticate directly with the module. Operators using the remote management application issue commands to the encryptor. Password based authentication is used between the management station and the module to authenticate each user. If the user is authenticated then Diffie-Hellman Key Agreement is employed to establish secure AES SNMPv3 privacy keys allowing the transport of secure messages to and from the module. Commands from the remote management application are individually authenticated to ensure Data Origin Authentication and Data Integrity. Data Origin Authentication, based on the names and passwords, ensures the authenticity of the user claiming to have sent the command. Users employing the module’s security functions and cryptographic algorithms, over the Data Input and Output ports, authenticate via certificates that have been generated and signed by a common Certificate Authority (CA). The modules exchange Key and Data Encryption keys using RSA public key wrapping. Alternatively, ECDH ephemeral key agreement is used for the purpose of establishing DEKs in accordance with NIST SP800-56A.

Table 8 Authentication Type

Role	Type of Authentication	Authentication Data
Administrator Supervisor (Crypto Officers)	Identity-based	Crypto Officers using the Local Console present unique user names and passwords to log in to the CLI. Crypto Officers using the remote management application have unique identities embedded in the command protocol. Each issued command is individually authenticated.
Operator Upgrader (Users)	Identity-based	Operators follow the same authentication rules as Crypto Officers.

The strength of the authentication mechanisms is detailed in Table 9.

Table 9 Strength of Authentication

Authentication Mechanism	Strength
Password	<p>Crypto Officers, Operators, and Upgraders accessing the module CLI, via the Local Console, must authenticate using a password that is at least 8 characters and at most 16 characters in length. The characters used in the password must be from the ASCII character set of alphanumeric and special (shift-number) characters. This yields a minimum of 62^8 (over 14.5 million) possible combinations. The possibility of correctly guessing a password is less than 1 in 1,000,000.</p> <p>After three failed authentication attempts via the CLI, the Local Console port access is locked for 3 minutes. With the 3 minute lockout, the possibility of randomly guessing a password in 60 seconds is less than 1 in 100,000.</p> <p>Note: The module also suppresses feedback of authentication data, being entered into the Local Console, by returning blank characters.</p>
Upgrade PIN	<p>Modules with Keypad and LCD functionality allow the module upgrade process to be initiated by selection of the upgrade image and correct entry of a 10-digit authentication PIN. Based on the keypad entry method, the possibility of randomly guessing and entering the correct PIN in 60 seconds is less than 1 in 100,000.</p>
User Certificates	<p>Far end modules (Users) authenticate using an RSA authentication certificate based on a 1024 or 2048 bit keys. The possibility of deriving a private RSA key is less than 1 in 1,000,000. Alternatively far end modules authenticate using an ECDSA authentication certificate using NIST P-256, P-384 or P-521 curves which provide 128, 192 and 256 bit key size equivalence respectively. The worst case probability of deriving an ECDSA private key is less than 1 in 1,000,000. Based on the multi-step handshaking process between modules, the possibility of randomly guessing the passphrase in 60 seconds is less than 1 in 100,000.</p>

4.2 Roles and Services

CN Series Ethernet Encryptors support the services listed in the following tables. The tables group the authorized services by the module's defined roles and identify the Cryptographic Keys and CSPs associated with the services. The modes of access are also identified per the explanation.

- R** - The item is **read** or referenced by the service.
- W** - The item is **written** or updated by the service.
- E** - The item is **executed** by the service (the item is used as part of a cryptographic function)
- D** - The item is **deleted** by the service.

The module's services are described in more detail in the CN Series documentation. Note access to and behaviour of module services are identical when operating in FIPS-Approved or non-Approved modes.

Once authenticated, the operator has access to the services required to initialize, configure and monitor the module. With the exception of passwords associated with user accounts, the operator never enters Cryptographic Keys or CSPs directly into the module (an Administrator CO will enter passwords when working with user accounts).

Table 10 Operator – Roles and Services

Crypto Officer		User		Authorized Service	Cryptographic Keys and CSPs	Access Type
Admin	Supv	Oper	Upgr			
✓	✓			Set Real Time Clock	none	W
✓				Load Module Certificate	RSA or ECDSA Public and Private Keys RSA or ECDSA Public Key Certificate	W W
✓				Create User Account	Password	W
✓				Modify User Account	Password	E, W
✓				Delete User Account	Password	D
✓	✓	✓	✓	View User Account	None	R
✓	✓			Edit Connection Action Table (Bypass)	none	W
✓	✓	✓	✓	View Connection Action Table	none	R
✓	✓	✓	✓	Show Firmware Version	none	R
✓				Clear Audit Trail	Password	W
✓	✓	✓	✓	View Audit Trail	none	R
✓				Clear Event Log	Password	W
✓	✓	✓	✓	View Event Log	none	R
✓	✓	✓	✓	View FIPS Mode Status	none	R
✓				Change FIPS Mode Status	Password	W
✓	✓			Run Self Test (Reboot Command)	Password	E
✓			✓	Install Firmware Upgrade	Password Keypad entered PIN	E
✓	✓			Generate Session Key (DEK)	AES DEKs ¹	W

Crypto Officer		User		Authorized Service	Cryptographic Keys and CSPs	Access Type
Admin	Supv	Oper	Upgr			
✓	✓			Generate Initialization Vector	Initialization Vector	W
✓	✓			RSA signature generation ^[3] .	RSA Private Key ³	R, E
✓	✓			RSA signature verification	RSA Public Key ³	R, E
✓	✓			ECDSA signature generation	ECDSA Private Key	R, E
✓	✓			ECDSA signature verification	ECDSA Public Key	R, E
✓				Erase Module – Zeroize (Console Command)	System Master Key and all CSP data stored in non-volatile memory	W
✓	✓			Establish a Remote Management Session	SNMPv3 Privacy Key ²	R, W, E

1. Restarting a connection causes new DEKs to be generated.
2. AES Privacy keys are established using Diffie-Hellman when an SNMPv3 remote management session is initiated and used to encrypt and decrypt all subsequent directives.
3. Although the module supports the creation and use of RSA keys < 2048 for signature generation they are non-compliant as per NIST SP800-131A.

Plaintext Cryptographic Keys and CSPs are never output from the module regardless of the operative role or the mode of operation.

5. Physical Security

CN Series Ethernet Encryptors employ the following physical security mechanisms:

1. The encryptor is made of commercially available, production grade components meeting commercial specifications for power, temperature, reliability, shock and vibration. All Integrated Circuit (IC) chips have passivation applied to them. The steel enclosure is opaque to the visible spectrum. The ventilation holes on the encryptor's front panel are factory fitted with baffles to obscure visual access and to prevent undetected physical probing inside the enclosure. Attempts to enter the module without removing the cover will cause visible damage to the module, while removing the cover will trigger the tamper circuitry.
2. Access to the internal circuitry is restricted by the use of tamper detection and response circuitry which is operational whether or not power is applied to the module. Attempting to remove the enclosure's cover immediately causes the module to be set into 'Discard' mode and initiates the zeroization of all Keys and CSPs. For further details refer to Section 6.2.
3. Two tamper evident seals are pre-installed (at factory). Both are placed between the top cover and underside of the main enclosure (refer Figure 16). Attempting to remove the top cover to obtain access to the internal components of the module will irreparably disturb these seals, thus providing visible evidence of the tamper attempt. Replacement tamper seals cannot be ordered from the supplier. A module with damaged tamper evident seals should be returned to the manufacturer by the Crypto Officer.

Figure 16 – CN6010 Factory installed tamper seals

Figure 17 – CN4010 Factory installed tamper seals

While the physical security mechanisms protect the integrity of the module and its keys and CSPs, it is strongly recommend that the cryptographic module be maintained within a physically secure, limited access room or environment.

Table 11 outlines the recommended inspection practices and/or testing of the physical security mechanisms.

Table 11 Physical Security Inspection & Test

Security Mechanism	Inspection & Test Guidance	Frequency
Tamper Evidence	<p>Tamper indication is available to all user roles via the alarm mechanism and evidence by the physical tamper labels.</p> <p>The Crypto Officer is responsible for the physical security inspection.</p> <p>During normal operation, the Secure LED is illuminated green. When the unit is not activated and/or uncertified (has no loaded certificate as either the default factory manufactured state or user erase operation has been executed) or in the tampered state, the Secure LED is illuminated red and all traffic is blocked. Inspect the enclosure and tamper evident seals for physical signs of tampering or attempted access to the cryptographic module.</p>	<p>In accordance with organization's Security Policy.</p>
Tamper Circuit	<p>The module enters the tampered state when the circuit is triggered. Once in this state, the module blocks all user traffic until the module re-activated and re-certified.</p>	<p>No direct inspection or test is required; triggering the circuit will block all data flow.</p>

6. Cryptographic Key Management

6.1 Cryptographic Keys and CSPs

The following table identifies the Cryptographic Keys and Critical Security Parameters (CSPs) employed within the module.

Table 12 Cryptographic Keys and CSPs

Key/CSP	Key Type and Use	Key/CSP Entry		Key/CSP Output		Key/CSP Destruction	Key/CSP Archiving
		Origin	Storage	Sourced	Format		
System Master Key	On initialization, the module generates a 168-bit symmetric key using the NIST SP800-90A DRBG. This key encrypts, using 3-key Triple-DES CFB8, the module's public and private RSA keys and the user table stored in the configuration flash memory.	Internal	Plaintext, in a tamper protected memory device	No	NA	On tamper or Erase ³ , the System Master Key is zeroized.	No
RSA Private Key(s)	A Private 1024 ⁴ or 2048 bit key is the secret component of the module's RSA Key pair. It is generated when the module receives a Load Certificate command from the remote management application. The RSA Private Key(s) are used to authenticate connections with other encryptors and to unwrap master session keys (KEKs) and session keys (DEKs) received from far-end encryptors.	Internal	3-key Triple-DES-encrypted format, non-volatile system memory.	No	NA	On tamper or Erase ³ , the Triple-DES System Master Key is zeroized, rendering the encrypted RSA Private Key undecipherable. Each event also deletes the RSA from non-volatile memory.	No
RSA Public Key(s)	This Public 1024 ⁴ or 2048 bit key is the public component of a module's RSA Key pair. They reside in the Network Certificate, and are used for authenticating connections with other encryptors.	Internal Electronic	3-key Triple-DES-encrypted format, in non-volatile system memory.	Electronic	Plaintext within X.509 certificate signed by trusted CA	On tamper or Erase ³ , the Triple-DES System Master Key is zeroized, rendering the encrypted RSA Public Key undecipherable. Each event also deletes the RSA keys from non-volatile memory.	No
ECDSA Private Key(s)	A Private ECDSA key using NIST P-256, P-384 or P-521 curves is the secret component of the module's ECDSA Key pair. It is generated when the module receives a Load Certificate command from the remote management application. The ECDSA Private Key(s) are used to authenticate connections with other encryptors.	Internal	3-key Triple-DES-encrypted format, non-volatile system memory.	No	NA	On tamper or Erase ³ , the Triple-DES System Master Key is zeroized, rendering the encrypted ECDSA Private Key undecipherable. Each event also	No

Key/CSP	Key Type and Use	Key/CSP Entry		Key/CSP Output		Key/CSP Destruction	Key/CSP Archiving
		Origin	Storage	Sourced	Format		
						deletes the ECDSA keys from non-volatile memory.	
ECDSA Public Key(s)	This Public ECDSA key using NIST P-256, P-384 or P-521 curves is the public component of a module's ECDSA Key pair. They reside in the Network Certificate, and are used for authenticating connections with other encryptors.	Internal Electronic	Stored in non-volatile system memory.	Electronic	Plaintext within X.509 certificate signed by trusted CA	The certificate is deleted from non-volatile system memory on tamper or Erase ³ command from a Crypto Officer.	No
ECDH Ephemeral Private Key	A Private ECDH ephemeral key using NIST P-256, P-384 or P-521 curves is the secret component of the ECDH key agreement key pair. It is generated during the key agreement process and destroyed once the process is complete.	Internal	Stored in volatile system memory.	No	NA	Exists in volatile memory during the key agreement process.	No
ECDH Ephemeral Public Key	This Public ECDH ephemeral key using NIST P-256, P-384 or P-521 curves is the public component of the ECDH key agreement key pair. It is generated during the key agreement process and destroyed once the process is complete.	Internal Electronic	Stored in volatile system memory.	Electronic	NA	Exists in volatile memory during the key agreement process.	No
Module Certificate(s)	A X.509 certificate is associated with a session in an operational environment. It is produced, upon request from the module, and signed by the Certificate Authority (CA) to establish root trust between encryptors. Once a certificate has been authenticated, Far-end encryptors use the signed RSA Public Key to wrap the initial session keys (KEKs) used to encrypt a session. Alternatively, far end encryptors use the signed ECDSA public key to authenticate messages sent during the ECDH key agreement process.	Internal Electronic	Stored, in the plaintext, in non-volatile system memory	Electronic	Plaintext signed by trusted CA	The certificate is deleted from non-volatile system memory on tamper or Erase ³ command from a Crypto Officer.	No

Key/CSP	Key Type and Use	Key/CSP Entry		Key/CSP Output		Key/CSP Destruction	Key/CSP Archiving
		Origin	Storage	Sourced	Format		
Authentication Password	<p>Up to 30 unique Crypto Officers (Administrator, Supervisor or Operator) may be defined, with associated passwords, within the module.</p> <p>The CLI uses the Authentication Password to authenticate Crypto Officers accessing the system via the Local Console.</p> <p>The remote management application requires an operator password that is used to uniquely authenticate each command to the module.</p>	Internal Electronic	<p>Passwords and their associated Usernames are hashed and stored in the User Table which is stored 3-key Triple-DES-encrypted format in non-volatile system memory</p>	No	NA	<p>On tamper or Erase³, the Triple-DES System Master Key is zeroized, rendering the encrypted Passwords undecipherable. Each event also deletes the User Table including passwords from non-volatile system memory</p>	No
Key Encrypting Key	<p>For each session (CI), the module generates a symmetric KEK using the NIST SP800-90A DRBG and other input in accordance with ATM Security Specification reference [10]. RSA key transport is used to transfer this key to a far-end module.</p> <p>The KEK persists for the life of the session and is used to secure the DEK that may be changed periodically during the session.</p>	Internal Electronic	<p>KEK is stored in plaintext, in volatile SDRAM system memory</p>	Yes	<p>Wrapped for transport using the far-end module's public RSA key</p>	<p>Zeroized at the end of a session, on tamper or Erase³ and when power is removed from unit</p>	No
Data Encrypting Key	<p>For each session (CI), the module also generates two DEK for each data flow path in the secure connection (one for the Initiator-Responder path and another for the Responder-Initiator path) using the NIST SP800-90A DRBG.</p> <p>For each ECDSA/ECDH based session (CI) a pair of encryptors use ECDH ephemeral key agreement to establish two DEKs for each data flow path in the secure connection (one for the Initiator-Responder path and another for the Responder-Initiator path).</p> <p>These keys AES encrypt and decrypt the user data transferred between the Encryptors.</p> <p>These active session keys are normally changed periodically based on the duration of the session.</p>	Internal Electronic	<p>DEK is stored in plaintext, in volatile SDRAM system memory</p>	Yes	<p>Encrypted using KEK in accordance with ATM Security Specification, reference [10]</p>	<p>Zeroized at the end of a session, on tamper or Erase³ and when power is removed from unit</p>	No

Group Establishment Key (GEK)	When a slave joins an ECDA/ECDH VLAN or multicast group session the key master from the group and the slave use ECDH ephemeral key agreement to establish a symmetric GEK used to wrap the group KEKs and DEKs using AES-256	Internal Electronic	Stored in volatile system memory.	Electronic	NA	Exists in volatile memory during the key agreement process.	No
SNMPv3 Privacy Keys	For each SNMPv3 remote management session, the module uses an AES privacy key as part of the Diffie-Hellman key agreement process to secure the control / flow path in the secure connection.	Internal Electronic	All SNMPv3 privacy keys are stored in plaintext, in volatile system memory	No	NA	Destroyed at the end of a remote management session and when power is removed from unit. Note Erase ³ , reboot and tamper will end a remote session	No
DRBG Seed	Used for SP800-90 Hash_DRBG the 440 bit seed value internally generated from nonce along with entropy input. A hardware based non-deterministic RNG is used for seeding the approved NIST SP 800-90 DRBG.	Internal	Stored in plaintext in volatile SDRAM system memory	Never exits the module	NA	Destroyed after each Hash_DRBG random data request and when power is removed from unit or rebooted	No
DRBG V Value	Used for SP800-90 Hash_DRBG, V is the Internal Hash_DRBG state value.	Internal	Stored in plaintext in volatile SDRAM system memory	Never exits the module	NA	Destroyed after each Hash_DRBG random data request and when power is removed from unit or rebooted	No
Diffie Hellman Private Keys	A private Diffie-Hellman key is the secret component of the Diffie-Hellman key pair. The key is created using Oakley group 14 for each remote management session to enable agreement of the SNMPv3 privacy key between the module and the management station.	Internal	Stored in plaintext, in volatile system memory	No	NA	Destroyed at the end of a remote management session and when power is removed from unit Note: Erase ³ , reboot and tamper will end a remote session	No

Diffie Hellman Public Keys	A public Diffie-Hellman key is the public component of the Diffie-Hellman key pair. The key is created using Oakley group 14 for each remote management session to enable agreement of the SNMPv3 privacy key between the module and the management station.	Internal	Stored in plaintext, in volatile system memory	No	NA	Destroyed at the end of a remote management session and when power is removed from unit Note: Erase ³ , reboot and tamper will end a remote session	No
-----------------------------------	--	----------	--	----	----	---	----

Note 1: While the certificates, maintained within the module, are listed as CSPs, they contain only public information.

Note 2: All random data including cryptographic Key material is sourced from the NIST SP800-90A DRBG as required

Note 3: Switching modes or selecting the front panel key press erase sequence initiates a module Erase resulting in the destruction of this Key/CSP.

Note 4: RSA with keys < 2048 bits are non-compliant in line with SP800-131A.

Note 5: The ECDH key agreement methodology as implemented in the module provides between 128 and 256 bits of encryption strength.

6.2 Key and CSP zeroization

Zeroization of cryptographic Keys and CSPs is a critical module function that can be initiated by a Crypto Officer or under defined conditions, carried out automatically. Zeroization is achieved using the “Zeroization sequence” defined in section 6.2.1 below.

Crypto Officer initiated zeroization will occur immediately when the:

1. Module Erase command issued from the CLI or remote management application
2. Front Panel key press Erase sequence is selected
3. Concealed front panel “Emergency” Erase button is depressed

Automatic zeroization will occur immediately when the module is:

1. Switched from an Approved to non-Approved mode of operation
2. Switched from an non-Approved to Approved mode of operation
3. Physically tampered

The following sections describe the specific events that occur when zeroization initiated. Note zeroization behaviour is the same whether the module is configured to run in FIPS-Approved or non-Approved mode.

6.2.1 Zeroization sequence

One initiated the module Zeroization sequence immediately carries out the following:

- Sets each session (CI) to DISCARD, before zeroizing the DEKs
- Zeroizes the System Master Key rendering the RSA and ECDSA Private Keys, User table (including authentication passwords) and other CSPs (Certificates, RSA keys) indecipherable
- Deletes all Certificate information
- Deletes RSA and ECDSA Private and Public keys, module Configuration and User table ²
- Automatically REBOOTS the module destroying KEKs, SNMPv3 Privacy and Diffie Hellman keys residing in volatile system memory

6.2.2 Erase command and key press sequence

A Crypto officer can initiate a module Erase remotely using the remote management application or when physically in the presence of the module using the management console CLI interface or Front Panel key press Erase sequence.

Zeroization of the module Keys and CSPs and is achieved using the zeroization sequence as defined in section 6.2.1.

6.2.3 Approved mode of operation

Switching the module to and from the FIPS Approved mode of operation will automatically initiate an Zeroization sequence to as defined in section 6.2.1 above.

² The RSA and ECDSA Private and Public keys, Configuration details and User table are encrypted by the System Master Key which, during an Erase, is the first CSP to be zeroized. Deleting the aforementioned CSPs is deemed good practise.

6.2.4 Tamper initiated zeroization

Zeroization will be initiated immediately upon detection of a tamper event. The Tamper Circuit is active at all times; the specific tamper response differs slightly based on the module's power state. From a practical standpoint the effect on the Keys and CSPs is the same.

The tamper initiated zeroization process achieves the following:

1. Zeroization of the System Master Key (SMK) rendering the RSA and ECDSA Private Keys, User table and other CSPs indecipherable. Zeroization of the SMK occurs irrespective of the powered state of the module.
2. When powered on and the Tamper Circuit is triggered, the module will automatically:
 - a. Set the encryption mode for each session (CI) to DISCARD ensuring no user data is output from the module,
 - b. Log the tamper event to the Audit Log,
 - c. Set the System, Secure and Alarm LEDs to flash RED on the front panel and herald the tamper event via the internal speaker,
 - d. Initiate the Zeroization sequence zeroizing all Session Keys (DEKs) and CSPs in volatile system memory and non-volatile Configuration and User account data,
 - e. REBOOT the module.
3. When powered off and the Tamper Circuit is triggered, there are no Session Keys (DEKs) or CSPs in system volatile memory to be zeroized however upon re-powering the module, the zeroized System Master Key will indicate that the system has been tampered. The module will:
 - a. Log the tamper event to the Audit log,
 - b. Initiate the Zeroization sequence,
 - c. Continue to the BOOT, returning the module to the un-Activated factory default state.
4. When the BOOT sequence has completed the module will have:
 - a. Generated a new System Master Key,
 - b. Re-created the default administration account,
 - c. Set the encryption mode to DISCARD,
 - d. Entered the factory default state ready for Configuration (as described in Section 8.3 below).

6.2.5 "Emergency" Erase

The "Emergency" Erase feature is initiated when the concealed front panel button is depressed and follows the behaviour defined in section 6.2.4 Tamper initiated zeroization above.

6.3 Data privacy

To ensure user data privacy the module prevents data output during system initialization. No data is output until the module is successfully authenticated (activated) and the module certificate has been properly loaded. Following system initialization, the module prevents data output during the self tests associated with a power cycle or reboot event. No data is output until all self tests have completed successfully. The module also prevents data output during and after zeroization of data plane cryptographic keys and CSPs; zeroization occurs when the tamper circuit is triggered. In addition, the system's underlying operational environment logically separates key management functions and CSP data from the data plane.

6.4 Cryptographic Algorithms

CN Series Ethernet Encryptors employ the following approved cryptographic algorithms. Table 13 lists approved embedded software algorithms that are common to the CN Series. Table 14 lists approved firmware algorithms that are specific to the CN4010 and CN6010 hardware versions.

Table 13 FIPS Approved Algorithms – CN Series Common Crypto Library

Algorithm Type	Algorithm	FIPS Validation Certificate	Target Model Notes
CN Series Common Crypto Library			CN4010 / CN6010
Symmetric Key	Triple-DES TCFB8 (e/d; KO 1)	Triple-DES #1905	
	AES CFB128 (e/d; 128,256)	AES #3335	
Asymmetric Key	RSA Key(gen) (MOD: 2048 PubKey Values: 65537) ALG[RSASSA- PKCS1_V1_5]; SIG(gen); 1024 ¹ , 2048; SIG(ver); 1024, 2048, SHS: SHA-1 ² , SHA- 256	RSA #1725	
	ECDSA NIST P-256, P-384 and P- 521 curves are supported and the hashing algorithms used with each of these are SHA-256, SHA-384 and SHA- 512 respectively in accordance with FIPS186-4.	ECDSA #659	
	ECDH NIST P-256, P-384 and P- 521 curves are supported. SHA-256 is used for key derivation in accordance with SP800-56A	KAS #56	
Hashing	SHA-1 (BYTE only) SHA-256 (BYTE only) SHA-384 (BYTE only) SHA-512 (BYTE only)	SHA #2770	
HMAC	HMAC-SHA-1 ³ . (Key Sizes Ranges Tested: KS<BS) HMAC-SHA-256 (Key Sizes Ranges Tested: KS<BS)	HMAC #2126	
DRBG	NIST SP800-90A Hash_Based DRBG: [Prediction Resistance Tested: Not Enabled (SHA-256)]	DRBG #777	

1. Although the module supports the creation and use of RSA keys < 2048 for signature generation they are non-compliant as per NIST SP800-131A.
2. SHA-1 shall not be used for digital signature generation in line with SP800-131A.
3. HMAC keys < 112 bits are non-compliant in line with SP800-131A.

Table 14 FIPS Approved Algorithms – CN Series Firmware Algorithms

Algorithm Type	Algorithm	FIPS Validation Certificate	Target Model Notes
CN4010 Module – Ethernet			Ethernet
Symmetric Key	AES CFB128 (e/d; 128, 256)	AES #3342	Selectable line rate of: 10/100/1000 Mbps
	AES CTR (int only; 128, 256)	AES #3342	Model number /description: A4010B:
	AES ECB (e; 128, 256)	AES #3342	1G Ethernet Encryptor
	AES GCM (e/d; 128, 256; Internal IV, AAD=128 to 688)	AES #3342	
CN6010 Module - Ethernet			Ethernet
Symmetric Key	AES CFB128 (e/d; 128, 256)	AES #3343	Selectable line rate of: 10/100/1000 Mbps
	AES CTR (int only; 128, 256)	AES #3343	Model number /description: A6010B:
	AES ECB (e; 128, 256)	AES #3343	1G Ethernet Encryptor
	AES GCM (e/d; 128, 256; Internal IV, AAD=128 to 688)	AES #3343	

In addition to the FIPS approved algorithms, the CN Series also includes the following non-Approved and Allowed algorithms.

Table 15 non-Approved and Allowed Algorithms

Function	Use
RSA Key Wrapping	RSA key wrapping using 2048 bit keys (112 bit equivalent strength) can be employed to establish the AES 128 or 256 bit symmetric keys used to secure encrypted connections between cryptographic modules.
ECDH Ephemeral Key Agreement	It is possible to configure an encryptor to use ECDH ephemeral key agreement with NIST P-256 (128 bit <i>equivalent strength</i>) or P-384 (192 bit equivalent strength) or NIST P-521 (256 bit equivalent strength) curves to establish the AES 256 bit symmetric keys used to secure encrypted connections between cryptographic modules. Only the use of P-521 will ensure that the established key maintains the full 256 bits of encryption strength.
Diffie-Hellman Key Agreement	Diffie-Hellman Key Agreement using 2048 bit Oakley Group 14 (112 bit equivalent strength) is employed to establish the AES 128 bit SNMPv3 privacy keys used to secure the management interface between the management application and the cryptographic module.

6.5 Key Derivation Functions

CN Series Ethernet Encryptors employ the following application-specific Key Derivation Functions (KDFs). Table 16 lists the KDFs.

Table 16 FIPS Approved KDF

KDF	Hash Algorithm	FIPS Validation Certificate	Target Model Notes
CN Series Common Crypto Library			CN4010 / CN6010
SNMP Privacy and Authentication Key	SHA-1	CVL (Cert.#489)	The SNMP protocol has not been reviewed or tested by the CAVP and CMVP

6.6 Non Approved and Allowed Security Functions

Table 17 Non-Approved and Allowed Security Functions

Function
A non-approved, non-deterministic RNG is used to seed the approved DRBG

7. Self Tests

CN Series cryptographic modules perform both power-up and conditional self tests to verify the integrity and correct operational functioning of the encryptor. Any failure of a self test will cause the module to transition to an error state and block all traffic on the data ports. Upon entering an error state an operator can attempt to clear the state by restarting the module. If the state cannot be cleared the module must be returned to the manufacturer. Table 18 summarizes the module's self tests.

The design of the CN Series cryptographic modules ensures that all data output, via the data output interface, is inhibited whenever the module is in a self-test condition. Status information displaying the results of the self tests is allowed from the status output interface. No CSPs, plaintext data, or other information, that if misused could lead to a compromise, is passed to the status output interface.

Upon successful completion of the self tests the module will allow access via the CLI and remote management tools. The LCD will display the set time and date as well as the time since successful reboot (self tests passed).

Table 18 Self Tests detail

Table Legend		
Halt (Secure)	Behaviour: The module will enter a Secure shutdown state and Halt ("Secure Halt"). Thereby preventing the module being configured and passing any data over the Network data output interface. Recovery: Attempt to recover by power-cycle. If the Secure Halt condition persists the module cannot be recovered and must be returned to the factory.	
Erase	Behaviour: The module will be Erased and reset to Factory Defaults. Recovery: Re-activate, certify and attempt to pass Network data.	
Error/Alarm	Behaviour: Error/Alarm logged. System state unchanged Recovery: Observe carefully and re-attempt, if error persists check "User Guide"	

Self Test	Description	Fault
Mandatory Tests	Performed at power-up and on demand	
Known Answer Tests	Each cryptographic algorithm, employed by the encryptor, is tested using a "Known Answer Test" to verify the operation of the function. CN Series KATs are divided into four distinct modules which correspond to the common modules listed in table 13 and firmware modules listed in table 14.	
CN Series Common Crypto Library	The following CN Series Common Crypto Library algorithms are tested: AES128 encrypt, AES128 decrypt, AES256 encrypt, AES256 decrypt, Triple-DES168 encrypt, Triple-DES168 decrypt, SHA-1, SHA-256, SHA-384, SHA-512, HMAC-SHA-1, HMAC-SHA-256, RSA2048 encrypt, RSA2048 decrypt, ECDSA P-256, P-384, and P-521 (Sign and Verify), ECDH P-256, P-384, and P-521 (primitive KAT) and SP 800-90A DRBG.	Halt
	Each of the AES firmware modules are tested at power-up. The CN4010 and CN6010 supports Ethernet mode.	
CN4010 Ethernet	AES CFB128 (e/d; 128, 256), CTR128 (e; 128, 256), GCM128 (e/d; 128, 256)	Halt

Self Test	Description	Fault
CN6010 Ethernet	AES CFB128 (e/d; 128, 256), CTR128 (e; 128, 256), GCM128 (e/d; 128, 256)	Halt
Firmware Integrity Test	An Error Detection Code (20-byte SHA-1 hash) is used to verify the integrity of all components within the cryptographic firmware when the module is powered up. Upon any file error the system will enter a Secure shutdown state and Halt ("Secure Halt")	Halt
Bypass Test	CN Series modules support alternating between Bypass, Discard and Encrypt modes (which can be seen from the management interface). The configuration files that control the bypass/discard and encrypt settings are integrity checked using a stored checksum (32 bit CRC). On power-up the module calculates a fresh checksum for all configuration files and compares each to the stored values. Upon a mismatch an error is flagged. The error condition will result in a recreation of the configuration file with the factory default settings. Factory default settings are to fail safe, setting policy to Discard. An audit message is entered to reflect the re-initialisation. Any user change (crypto officer) to or from encrypt, bypass or discard shall cause an audit log entry.	Erase
Critical Functions	Performed at power-up	
Battery	The battery voltage is tested to determine if it is critically low. This test is guaranteed to fail prior to the battery voltage falling below the minimum specified data retention voltage for the associated battery-backed components. If this test fails, the battery low alarm condition is raised. The module continues to operate however it is advisable that the battery be replaced immediately. The battery is located in the removable fan tray and can be ordered from the module's supplier. Battery alarm indication is available to all user roles via the alarm mechanism.	Alarm
Real Time Clock / Tamper Memory	The Real Time Clock (RTC) oscillator is checked at start-up and the Tamper memory is examined for evidence of a Tamper Condition.	Halt
Conditional Tests	Performed, as needed, during operation	
Bypass Test	The module supports alternating between Bypass, Discard and Encrypt modes (which can be seen from the management interface). The configuration files that control the bypass/discard and encrypt settings are integrity checked using a stored checksum (32 bit CRC). Conditional bypass tests are enforced by checking the CRC during each process initialisation that memory maps specific configuration data. If the CRC is valid, the process continues execution with that data, otherwise a re-initialisation is executed to failsafe values. Once running, a process will update the relevant configuration data when required, recalculating and storing the new CRC value.	Erase
Pair-wise Consistency	RSA Public and Private keys are used for the calculation and verification of digital signatures and for key transport.	Halt

These keys are tested for consistency, based to their purpose, at the time they are generated. RSA wrapping keys are tested by an encrypt/decrypt pair-wise consistency test; signature keys are tested by a sign/verify pair-wise consistency test.

ECDSA Public and Private keys are used for the calculation and verification of digital signatures. These keys are tested for consistency at the time they are generated with a sign/verify pair-wise consistency test.

Firmware Load	The module verifies the authenticity of any firmware load that is applied to the encryptor in the field. Only firmware loads with a valid and verified RSA signature are accepted.	Error
Continuous DRBG	The non-deterministic RNG is continuously tested according to SP800-90B (section 6.5.1). The DRBG is continuously tested according to FIPS140-2 (section 4.9.2).	Halt

Crypto Officers can run the power-up self-test on demand by issuing a module reboot command. This may be accomplished via the Local Console, or by cycling the power to the module. Use of the Local Console or power cycling the module requires a direct connection or physical access to the module respectively. Rebooting or power cycling the module causes the keys securing the configured connections to be re-established following the restoration of communications.

8. Crypto-Officer and User Guidance

This section provides information for Crypto Officers to install, configure and operate the CN Series Ethernet Encryptors in FIPS mode.

As outlined in this Security Policy, Crypto Officers (more specifically, Administrators and Supervisors) are the only administrators/operators that can make configuration changes or modify the system settings. The Crypto Officer is responsible for the physical security inspection.

The CN Series is designed to operate in either a FIPS approved mode or a non-FIPS approved mode. The operator can query the FIPS status (operating mode) of a module, and authorized operators may change the FIPS mode of operation. The FIPS status can be queried from the Local Console via the CLI or remotely via the remote management application.

To ensure that no CSPs are accessible from a previous operating mode a module Erase and Reboot are automatically performed upon mode change.

Note: Non-FIPS mode of operation is provided for interoperability with legacy systems. The module's factory default (Erased) mode is FIPS approved and the CN Series Ethernet Encryptor modules must be explicitly configured to operate in a non-FIPS approved mode.

The console command is:

```
> fips on<ENTER>
```

```
CN6010> fips on  
FIPS mode enabled
```

The Senetas CM remote management application screen for reporting the FIPS status is found on the User Management screen, in the Access tab under FIPS PUB 140-2 Mode.

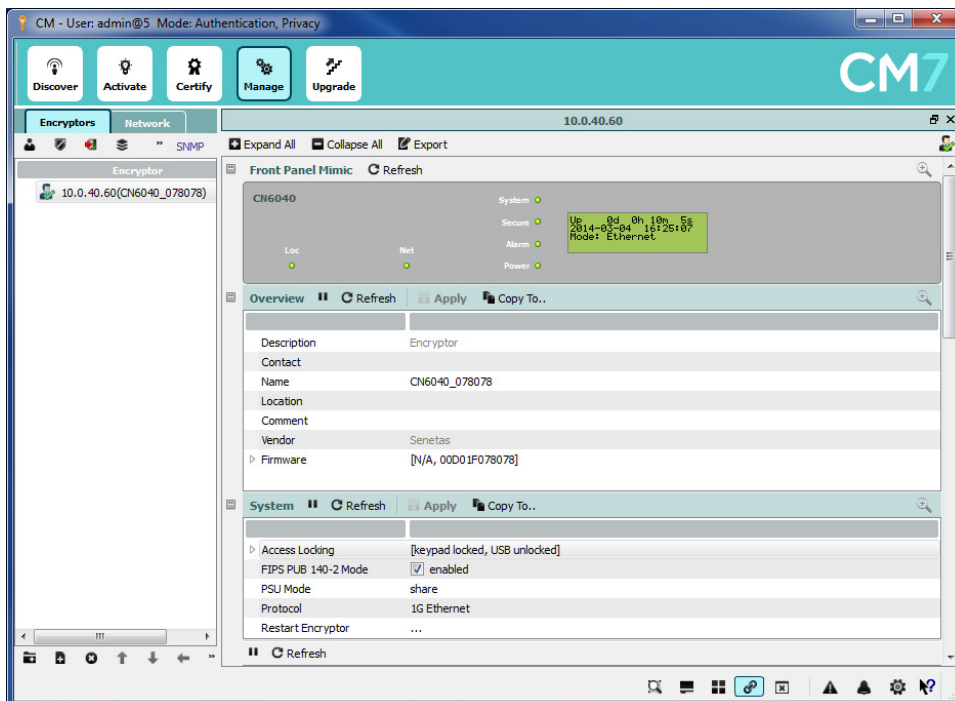

Figure 18 – FIPS Approved and non-Approved mode selection

Note: Read all of the instructions in this section before installing, configuring, and operating the CN Series Encryptors.

8.1 Delivery

When a CN Series Encryptor is delivered, the CO can verify that the model and serial numbers on the outside of the packaging, the model and serial numbers attached to the encryptor itself, and the numbers listed on the order acknowledgement, all match. The CO can also verify that the encryptor has not been modified by examining the tamper evident seal on the outside of the unit. If the seal is broken, then the integrity of the encryptor cannot be assured the supplier should be informed immediately.

Upon receipt of a CN Series Encryptor, the following steps should be undertaken:

1. Inspect the shipping label as well as the label on the bottom of the system to ensure it is the correct FIPS-approved version of the hardware.
2. Inspect the encryptor for signs of tampering. Check that the tamper evident tape and the covers of the device do not show any signs of tampering. If tampering is detected, return the device to the manufacturer.

Do not install the encryptor if it shows signs of tampering or has an incorrect label. Contact your organization's Security Officer for instructions on how to proceed.

If the device has the correct label and shows no signs of tampering, proceed to the next section.

8.2 Location

The encryptor must be installed in a secure location to ensure that it cannot be physically bypassed or tampered with. Ultimately the security of the network is only as good as the physical security around the encryptor.

Always maintain and operate the CN Series Encryptor in a protected/secure environment. If it is configured in a staging area, and then relocated to its operational location, never leave the unit unsecured and unattended.

Ideally the encryptor will be installed in a climate-controlled environment with other sensitive electronic equipment (e.g. a telecommunications room, computer room or wiring closet). The encryptor can be installed in a standard 19-inch rack or alternatively mounted on any flat surface. Choose a location that is as dry and clean as possible. Ensure that the front and rear of the encryptor are unobstructed to allow a good flow of air through the fan vents.

The encryptor is intended to be located between a trusted and an untrusted network. The Local Interface of the encryptor is connected to appropriate equipment on the trusted network and the Network Interface of the encryptor is connected to the untrusted (often public) network.

Depending on the topology of your network, the Local Interface will often connect directly to a router or switch, while the Network Interface will connect to the NTU provided by the network carrier.

8.3 Configuration – FIPS140-Approved mode

Full configuration instructions are provided in the **User Manual**. Use the guidance here to constrain the configuration so that the device is not compromised during the configuration phase. This will ensure the device boots properly and enters FIPS 140-2 approved mode.

When powering up the module for the first time, use the front panel to configure the system for network connectivity. Then use the remote management application to initialize the module and perform the configuration operations.

1. Power on the unit.

The system boot-up sequence is entered each time the module is powered on and after a firmware restart. The CN Series Encryptor automatically completes its self tests and verifies the authenticity of its firmware as part of the initialization process. The results of these tests are reported on the front panel LCD and are also logged in the system audit log.

If errors are detected during the diagnostic phase, the firmware will not complete the power up sequence but will instead enter a Secure shutdown state and Halt ("Secure Halt"). If this occurs the first time power is applied or any time in the future, the module is notifying the CO

that a persistent (hard) error has occurred and that the module must be returned for inspection and repair.

2. Follow the User Manual's **Commissioning** section to set the system's IP Address, Date and Time.
3. If the CM application is being run for the first time, it will ask if the installation will act as the Certification Authority (CA) for the secure network. If the user selects yes a private and public RSA or ECDSA key pair that will be used to sign X.509 certificates is generated.

4. **Activate** the cryptographic module.

A newly manufactured or erased cryptographic module must be **Activated** before X.509 certificate requests can be processed. See the User Manual's **Commissioning** section for details.

Activation ensures that the default credentials of the 'admin' account are replaced with those specified by the customer prior to loading signed X.509 certificates in to the module.

The updated user credentials (username and password) are transmitted to the encryptor using RSA 2048 public key encryption, and a hashing mechanism is used by the local administrator CO to authenticate the message.

5. Install a signed **X.509 certificate** into the cryptographic module.

Version 2.2.0 and later CN Series cryptographic modules support V1/V2 and V3 X.509 Certificate Signing Requests (CSRs) and will accept certificates signed by the remote management application (when acting as a CA) as well as certificates signed by External CAs. In both cases each CN Series cryptographic module supplies upon request an unsigned X.509 certificate containing the module's details and 1024 or 2048 bit Public RSA key or an ECDSA Public key using NIST P-256, P-384 or P-521 curves.

The administrator then takes the CSR and has it signed by either the trusted local CA (the remote management application for V1/2/3 certificates) or an external CA for V3 certificates. For a typical deployment this procedure is repeated for all cryptographic modules in the network and the signed certificates are installed in to each module.

After an X.509 certificate has been installed into CN Series module the administrator can create supervisor and operator accounts.

At this point the CN Series Encryptor is able to encrypt in accordance with the configured security policy; the ENT key on the front panel is disabled; and the default factory account has been removed.

6. Ensure the encryptor is in FIPS 140-2 mode (default setting) via the Senetas CM remote management applications' **Management-Access** tab. See Figure 18 for details.
7. Configure the security policy to enable encrypted tunnels with other CN Series modules.
Configuration of the security policy is network specific; refer to the User Manual for specific details.

8.4 Configuration - non-Approved mode

CN Series Ethernet Encryptors are capable of operating in a non-Approved mode in order to interwork with legacy management systems that are unable to support SNMPv3 privacy. All other module services are identical and no additional Keys/CSPs are accessible.

Configuring the Encryptor into non-Approved mode of operation can be achieved using the CM remote management application or the local console via CLI. Once the change is affected the module will automatically erase and restart:

1. Navigate to the FIPS PUB 140-2 setting in **Management-Access** tab within the CM Application and *SET* the *Disable FIPS PUB 140-2 Mode* checkbox
– OR –
2. Login via the front panel management console and execute the console command e.g. “*CN6010 Encryptor> fips off*”. See Figure 18 for details.

Upon restart, the FIPS mode state can be checked using the remote management application or local console.

9. Mitigation of Other Attacks

The module can be configured to mitigate against traffic analysis attacks on point-to-point connections using the TRANSEC feature.

The module does not mitigate against any other specific attacks.

9.1 TRANSEC

Traffic Analysis is the process of intercepting and examining messages in order to deduce information from patterns in communication. It can be performed even when the messages are encrypted and cannot be decrypted. TRANSEC is transmission security and is used to disguise patterns in network traffic to prevent Traffic Analysis.

A TRANSEC enabled module exhibits the following encryption characteristics:

- Generates and transmits fixed size encrypted Ethernet frames at a constant frame rate from the WAN facing network port.
- Encrypts the entire Ethernet frame received on the local port so that no MAC addresses, other header information or payload data is exposed.
- The rate of the transmitted Ethernet frame is constant and independent of the received plaintext traffic rate from the local port.
- In the absence of user data from the local port the TRANSEC encryptor module fills the transmitted frames with pseudo random or encrypted data such that it cannot be distinguished from encrypted user data.
- TRANSEC encryptor modules default to decrypting traffic received on their network interface and discard all introduced traffic that is not 'real' user data.

End
