## 1. Module Overview

The SecureParser® (SW Version 4.7.1) is a FIPS software-only module (hereafter known as “the module”) that operates on a multi-chip standalone general purpose computer. The module is a security and data availability architecture delivered in the form of a toolkit that provides cryptographic data splitting (data encryption, random or deterministic distribution to multiple shares including additional fault tolerant bits, key splitting, authentication, integrity, share reassembly, key restoration and decryption) of arbitrary data. The SecureParser accepts any type of digital data and cryptographically splits it into shares so that no discernible plaintext is transmitted across a network or is placed on a single storage device. During the parse process, additional redundant data may be optionally written to each share enabling the capability of restoring the original data when all shares are not available. The shares can be stored in geographically disbursed nodes providing for continuous access to online information.

Each share contains a cryptographically strong integrity check that prevents tampering with the stored data and is immediately recognized by the other shares. Any change to the data in a share precludes that share from being used in the data rebuild process. The encryption, integrity and Information Dispersal Algorithm (IDA) session keys are encrypted with long-term, external workgroup keys, and a per-session key encrypting key that is shared and stored with the data.

Data availability through redundant shares allows for a return to operations in the face of lost or corrupted shares due to environmental, malicious or accidental catastrophes.

The SecureParser module is designed to be integrated at any point where data is written, retrieved, sent or received.

### Boundaries

**Physical Boundary** (case of general purpose computer)

**Figure 1 – Block Diagram of the Cryptographic Module**

### **Logical Boundary**

When operating on the Linux and UNIX operating systems, the SecureParser cryptographic logical boundary is defined as containing the SecureParser libparser4.so. Seed values for the SecureParser's random number generator are imported from standard operating system services within the physical boundary of the general purpose computer.

When operating on Microsoft Windows, the SecureParser module cryptographic logical boundary is defined as containing the SecureParser libparser4.dll. Seed values for the SecureParser's random number generator are imported from standard operating system services within the physical boundary of the general purpose computer.

### **Physical Boundary**

The SecureParser cryptographic physical boundary is the case of the General Purpose Computer (GPC) on which the libparser4 executable is instantiated. Ports at the physical boundary of the GPC are those typical of a GPC for connecting external devices such as keyboards, monitors, mice, and printers. These devices are outside the physical boundary of the cryptographic module and are outside the scope of the validation.

### **Operating Systems & Platforms**

The SecureParser module has been tested on and found to be conformant with the requirements of FIPS 140-2 overall Level 1 on the following GPC operating systems:

| Operating System           | Hardware Platform                                              | Module File Name |
|----------------------------|----------------------------------------------------------------|------------------|
| Microsoft Windows 8 64-bit | Lenovo ThinkPad X140e<br>(AMD E1 with AES-NI)                  | libparser4.dll   |
| Microsoft Windows 8 64-bit | Lenovo ThinkPad X140e<br>(AMD E1 with AES-NI disabled)         | libparser4.dll   |
| Microsoft Windows 7 64-bit | Dell Inspiron 660<br>(Intel Core i5-3xxx with AES-NI)          | libparser4.dll   |
| Microsoft Windows 7 64-bit | Dell Inspiron 660<br>(Intel Core i5-3xxx with AES-NI disabled) | libparser4.dll   |
| Android 4.4                | Samsung Galaxy S5<br>(Qualcomm Snapdragon 800 series)          | libparser4.so    |
| Android 5.0                | Samsung Galaxy Note 3<br>(Qualcomm Snapdragon 800 series)      | libparser4.so    |
| Android 4.4                | Samsung Galaxy Note 4<br>(Qualcomm Snapdragon 800 series)      | libparser4.so    |

Operational testing was performed on all the above operating systems.

## 2. Security Level

The cryptographic module meets the overall requirements applicable to Level 1 security of FIPS 140-2.

**Table 1 – Module Security Level Specification**

| <b>Security Requirements Section</b> | <b>Level</b> |
|--------------------------------------|--------------|
| Cryptographic Module Specification   | 3            |
| Module Ports and Interfaces          | 1            |
| Roles, Services and Authentication   | 1            |
| Finite State Model                   | 1            |
| Physical Security                    | N/A          |
| Operational Environment              | 1            |
| Cryptographic Key Management         | 1            |
| EMI/EMC                              | 3            |
| Self-Tests                           | 1            |
| Design Assurance                     | 3            |
| Mitigation of Other Attacks          | N/A          |

### 3. Modes of Operation

#### **Approved Algorithms**

In the FIPS Approved mode, the SecureParser module supports FIPS Approved algorithms as follows. The certificate #'s cited below have all been obtained by SecureParser module algorithm testing with the CAVP:

#### **Software (CPU) Algorithms:**

|                                                            |             |
|------------------------------------------------------------|-------------|
| AES-CBC/ECB - 128/192/256 bit key                          | Cert. #3365 |
| AES-CTR - 128/192/256 bit key                              | Cert. #3365 |
| AES-GCM 128/192/256 bit key                                | Cert. #3365 |
| HMAC-SHA1, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512           | Cert. #2145 |
| SHA-1, SHA-256, SHA-384, SHA-512 hashing                   | Cert. #2790 |
| RSA verify – 1024/2048/3072 bit key with SHA-1/256/384/512 | Cert. #1729 |
| RSA Key Gen, sign – 2048/3072 bit key with SHA-256/384/512 | Cert. #1729 |
| SP800-90A CTR_DRBG with AES-256                            | Cert. #793  |
| ECDSA verify – P-521 with SHA-1/256/384/512                | Cert. #668  |
| ECDSA Key Gen, sign – P-521 with SHA-256/384/512           | Cert. #668  |

#### **Allowed Key Entry and Output**

All Key Entry and Output in the FIPS Approved mode must be in encrypted form. Plaintext keys are never entered or output from the module.

**Key Wrapping** per FIPS 140-2 IG D.9 using 128/192/256 bit keys. AES (*Cert. #3365 key wrapping; key establishment methodology provides between 128 and 256 bits of encryption strength*)

**RSA Key Encapsulation** per FIPS 140-2 IG D.9 using  $k = 3072$ . RSA (*key wrapping; key establishment methodology provides 128 bits of encryption strength*).

The SecureParser module does not support any non-allowed FIPS algorithms.

#### **Configuring the module for FIPS Approved mode**

The SecureParser module may be configured for the FIPS Approved mode by calling the module's exposed `module_initialize()` API function with the calling parameter "fipsEnabled" set to true. Subsequent SecureParser module API calls that are used to further configure the SecureParser will have their calling parameters checked by the SecureParser based on the value of the "fipsEnabled" calling parameter used in the original `module_initialize()` API function call. These subsequent checks are used to insure that all FIPS Approved mode configuration values are set properly.

Operators can determine if the cryptographic module is running in the FIPS Approved or non-FIPS Approved mode via execution of the module's `module_getStatus()` API function call, which is used to meet the FIPS area 1 requirements to achieve Level 3. The `module_getStatus()` API function call equates to the FIPS "show status" service and will indicate if the FIPS

Approved mode of operation has been selected. The module\_getStatus( ) API call returns two items:

- Whether the module is in the FIPS Approved mode (value set = 1), or non-FIPS Approved mode (value set = 0)
- The current FSM state of the module (MODULE\_STATE enum)

Once the FIPS Approved mode of operation has been selected the module cannot transition into the non-FIPS Approved mode of operation during the lifetime of the module instantiation in executable memory. Similarly once the non-FIPS Approved mode of operation has been selected the module cannot transition into the FIPS Approved mode of operation during the lifetime of the module instantiation in executable memory.

### ***Non-FIPS Approved mode of operation***

The SecureParser module can be initialized into a non-FIPS Approved mode of operation by setting the “fipsEnabled” flag to 0 during the first call to the API function module\_initialize( ).

In the non-FIPS Approved mode, the module allows encryption and/or message authentication to be disabled.

Applications cannot transition their use of the module toolkit library to/from the FIPS Approved mode and non-FIPS Approved mode while the module is instantiated. The module must be shut down by the calling application and then restarted to transition to/from the FIPS Approved mode and non-FIPS Approved mode. Note that the module does not have any persistent CSPs. All CSPs are zeroed when the module is shut down or transitions between modes.

## 4. Identification and Authentication Policy

### *Assumption of roles*

The module does not provide an authentication mechanism, the operating systems hosting the module have authentication implemented. The module implements User and Crypto-Officer roles.

The User and Crypto-Officer roles are assumed by the operator accessing services provided by the module.

## 5. Access Control Policy

### *Roles and Services*

#### **Services:**

- **module\_initialize.** Initializes the module, sets FIPS Approved mode or non-FIPS Approved mode, performs self-tests, and moves the module into an operational state.
- **parser\_create.** Allocates the memory for a Parser structure. There can be multiple parser instances within the module – they are all either in FIPS Approved mode, or they are all in non- FIPS Approved mode (determined by the module\_initialize service).
- **parser\_destroy.** Deallocates the memory of a Parser structure.
- **parser\_generateHeaders.** Configures parser context and generates headers.
- **parser\_restoreHeaders.** Configures parser context based on headers with optional modifications.
- **parser\_regenerateHeaders.** Produces headers associated with an already-configured parser context.
- **parser\_recoverHeaders.** Recovers missing headers and places them in the output buffers that are unused.
- **parser\_setWorkgroupKeys.** Changes the workgroup keys in an existing parser context.
- **keystore\_getImportKey.** Provides the RSA public key needed for asymmetric key wrapping for all key entry into the specified keystore of the module (note that each keystore will have its own ephemeral public/private keypair).
- **keystore\_create.** Allocates memory for a volatile KeyStore structure, and creates a non- persistent RSA public/private encryption keypair to be used for key import (note that each keystore will have its own public/private keypair).
- **keystore\_destroy.** Deallocates the memory of a volatile KeyStore structure.
- **keystore\_addKeyFromBuffer.** Imports a key into the specified volatile keystore structure. All imported keys will be RSA key wrapped and will need to be unwrapped by the module. Note: x509 certificates can be in the buffer, their public keys will be imported.
- **keystore\_removeKey.** Removes a key from the volatile keystore.
- **keystore\_getKeyType.** Returns the key type for the requested key.

- **keystore\_getkeylength.** Returns the key length for the requested key.
- **keystore\_keyexists.** True or False, the requested key exists or does not exist within the specified volatile keystore.
- **module\_destroy:** Zeroization, called by the application prior to (graceful) application termination. Zeroes non-persistent CSPs including the RSA import public/private keypair, and the volatile Keystores. ALL keystores and ALL parsers in memory are zeroed.
- **parser\_parseData.** Parses data from the input buffer into the output buffers.
- **parser\_restoreData.** Restores data from the output buffers into the input buffer.
- **parser\_parseDataEx.** Parses an array of input buffers into the output buffers.
- **parser\_recoverData.** Rebuilds all N data shares given only M input shares.
- **parser\_getFieldOffsets.** Returns an array of {share number, offset, length} tuples necessary to create M of N shares for a given M value and a set of “N of N” parsed shares.
- **parser\_setFaultTolerance.** Sets a new fault tolerance value (M). Designed for use with parser\_getFieldOffsets().
- **parser\_getHeaderInfo.** Processes the header and returns information about specific header fields.
- **parser\_getParsedLength.** Returns the number of bytes needed for each output share when parsing.
- **parser\_getRestoredLength.** Returns the number of bytes needed for the original share when restoring.
- **module\_getStatus:** This service provides the current status of the cryptographic module including whether or not a FIPS Approved mode of operation has been selected.
- **Self-tests:** Power cycle

**Table 5 – Specification of Service Inputs & Outputs**

| Service           | Control Input   | Data Input | Data Output  | Status Output         |
|-------------------|-----------------|------------|--------------|-----------------------|
| module_initialize | int fipsEnabled | N/A        | N/A          | Success or ERROR_TYPE |
| parser_create     | N/A             | N/A        | Parser **ret | Success or ERROR_TYPE |
| parser_destroy    | Parser *p       | N/A        | N/A          | Success or            |

| Service                    | Control Input                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Data Input              | Data Output                                             | Status Output            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|---------------------------------------------------------|--------------------------|
|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                         |                                                         | ERROR_TYPE               |

### **Definition of Critical Security Parameters (CSPs)**

The following are CSPs contained within the module:

- **Private\_Import\_Key\_RSA\_Unwrap:** Used by the SecureParser module to unwrap encrypted keys sent to it by applications. All keys sent to the SecureParser will be RSA key wrapped by applications with CSP **Public\_Import\_Key\_RSA\_Wrap**. Note that each SecureParser keystore will have its own associated RSA public/private import keypair.
- **Workgroup\_Key\_Enc:** Used to key wrap internally generated encryption session key (Session\_Key\_Enc), also used to unwrap encryption session key when headers are being restored.
- **Workgroup\_Key\_Mac:** Used to key wrap internally generated integrity session key (Session\_Key\_Mac), also used to unwrap integrity session key when headers are being restored.
- **Workgroup\_Key\_Ida:** Used to key wrap internally generated IDA session key (Session\_Key\_Ida), also used to unwrap IDA session key when headers are being restored.
- **Session\_Key\_Enc:** Used to encrypt all plaintext data prior to data splitting. Encrypted by Workgroup\_Key\_Enc using the Key wrap and then placed into share headers.
- **Session\_Key\_Mac:** HMAC-SHA1, SHA256, SHA384, or SHA512 key used for ciphertext data integrity once splitting is complete. Encrypted by Workgroup\_Key\_Mac using the NIST Key wrap and then placed into share headers.
- **Session\_Key\_Ida:** Random seed used as input to IDAs for adding randomness. Encrypted by Workgroup\_Key\_Mac using the Key wrap and then placed into share headers.
- **Share\_Integrity\_Key\_HMAC:** Optional HMAC-SHA1, HMAC-SHA256, HMAC-SHA384, or HMAC-SHA512 key used for additional ciphertext share data integrity after data splitting. Never output.
- **Share\_Integrity\_Key\_RSA\_Sign:** Optional RSA Private Key used to sign ciphertext share data after the data splitting process. Never output.
- **Share\_Integrity\_Key\_ECDSA\_Sign:** Optional ECDSA Private Key (PEM or ANSI) used to sign ciphertext share data after the data splitting process. Never output.
- **DRBG\_Seed\_Value:** Imported from standard operating system services within the physical boundary of the general purpose computer. Used to seed the module's own FIPS SP 800-90A DRBG. **The DRBG seed comes from the operating system, which is outside the logical boundary of the module but within the physical boundary. The seed is assumed to have at least 256-bits of security strength. The seed length is 384 bits.**
- **SecureParser DRBG\_State:** Internal state of the SecureParser's DRBG (Cert. #793).

### **Definition of Public Keys**

The following are the public keys contained in the module:

- **Public\_Import\_Key\_RSA\_Wrap:** Used by applications to wrap keys they are sending to the SecureParser module. All keys sent to the SecureParser must be RSA wrapped. Note that each SecureParser keystore will have its own public/private key pair.
- **SW\_Integrity\_Key\_RSA\_Verify:** Used for verification of the signed module executable during power-on self-tests. Hard coded in the module.
- **Share\_Integrity\_Key\_RSA\_Verify:** Optional RSA Public Key used to verify ciphertext share data during the restoration process. Can be imported into the module from an X509

- **Share\_Integrity\_Key\_ECDSA\_Verify:** Optional ECDSA Public Key (PEM or ANSI) used to verify ciphertext share data during the restoration process. Can be imported into the module from an X509 certificate.

### Definition of CSPs Modes of Access

Table 6 defines the relationship between access to CSPs and the different module services. The modes of access shown in the table are defined as follows:

- G = Generate CSP
- R = Read CSP
- W = Write CSP
- Z = Zero CSP

**Table 6 – CSP Access Rights within Roles & Services**  
**Ref. SecureParser Specification: 4.4 Critical Security Parameters**

For each service listed in Table 6 above, the following identifies all CSPs that are entered into and output from the module during execution of each service.

- module\_initialize:
  - Entry: N/A.
  - Output: N/A.
- parser\_create:
  - Entry: N/A.
  - Output: N/A.
- parser\_destroy:
  - Entry: N/A.
  - Output: N/A.
- parser\_generateHeaders:
  - Entry: N/A.
  - Output:
    - f* Session\_Key\_Enc (encrypted with Workgroup\_Key\_Enc).
    - f* Session\_Key\_Mac (encrypted with Workgroup\_Key\_Mac).
    - f* Session\_Key\_Ida (encrypted with Workgroup\_Key\_Ida).
- parser\_restoreHeaders:
  - Entry:
    - f* Session\_Key\_Enc (encrypted with Workgroup\_Key\_Enc).
    - f* Session\_Key\_Mac (encrypted with Workgroup\_Key\_Mac).
    - f* Session\_Key\_Ida (encrypted with Workgroup\_Key\_Ida).
  - Output: N/A.

- parser\_regenerateHeaders:
  - o Entry: N/A.
  - o Output:
    - f Session\_Key\_Enc (encrypted with Workgroup\_Key\_Enc).
    - f Session\_Key\_Mac (encrypted with Workgroup\_Key\_Mac).
    - f Session\_Key\_Ida (encrypted with Workgroup\_Key\_Ida).
- parser\_recoverHeaders:
  - o Entry:
    - f Session\_Key\_Enc (encrypted with Workgroup\_Key\_Enc).
    - f Session\_Key\_Mac (encrypted with Workgroup\_Key\_Mac).
    - f Session\_Key\_Ida (encrypted with Workgroup\_Key\_Ida).
  - o Output:
    - f Session\_Key\_Enc (encrypted with Workgroup\_Key\_Enc).
    - f Session\_Key\_Mac (encrypted with Workgroup\_Key\_Mac).
    - f Session\_Key\_Ida (encrypted with Workgroup\_Key\_Ida).
- parser\_setWorkgroupKeys:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_create:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_destroy:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_addKeyFromBuffer:
  - o Entry:
    - f Workgroup\_Key\_Enc (encrypted with Public\_Import\_Key\_RSA\_Wrap).
    - f Workgroup\_Key\_Mac (encrypted with Public\_Import\_Key\_RSA\_Wrap).
    - f Workgroup\_Key\_Ida (encrypted with Public\_Import\_Key\_RSA\_Wrap).
    - f Share\_Integrity\_Key\_HMAC (encrypted with Public\_Import\_Key\_RSA\_Wrap).
    - f Share\_Integrity\_Key\_RSA\_Sign (encrypted with Public\_Import\_Key\_RSA\_Wrap).
    - f Share\_Integrity\_Key\_ECDSA\_Sign (encrypted with Public\_Import\_Key\_RSA\_Wrap).
  - o Output: N/A.
- keystore\_removeKey:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_getKeyType:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_getKeyLength:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_keyExists:
  - o Entry: N/A.
  - o Output: N/A.
- keystore\_getImportKey:

- o Entry: N/A.
  - o Output: Public\_Import\_Key\_RSA\_Wrap (plaintext).
- parser\_parseDataEx:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_parseData:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_restoreData:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_recoverData:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_getHeaderInfo:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_getFieldOffsets:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_setFaultTolerance:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_getParsedLength:
  - o Entry: N/A.
  - o Output: N/A.
- parser\_getRestoredLength:
  - o No key Entry or Output.
- module\_getstatus:
  - o Entry: N/A.
  - o Output: N/A.
- Zeroization: module\_destroy:
  - o Entry: N/A.
  - o Output: N/A.
- Self tests (power cycle):
  - o Entry: N/A.
  - o Output: N/A.

## 6. Security Rules

The SecureParser cryptographic module's design corresponds to the module's security rules. This section documents the security rules enforced by the cryptographic module to implement the security requirements of this FIPS 140-2 Level 1 software-only module.

1. The SecureParser module interfaces are logically distinct from each other as defined by the SecureParser API for the following interfaces: Data Input; Data Output; Control Input; Status Output.
2. Status information does not contain CSPs or sensitive data that if misused could lead to a compromise of the module.
3. Data output is inhibited during self-tests, and while in error states.
4. Data output is disconnected from the module processes that perform key generation, and plaintext CSP zeroing (the module will not support manual key entry).
5. Two independent internal actions are required to output data via the output interface through which sensitive restored plaintext share data is output.
6. Plaintext secret/private key output is not supported. No SecureParser API calls will permit secret/private key output.
7. The SecureParser module shall provide two distinct operator roles. These are the User role, and the Cryptographic-Officer role.
8. The SecureParser module does not support concurrent operators.
9. The SecureParser module does not support a maintenance role.
10. The SecureParser module does not support a bypass capability.
11. The SecureParser module provides identity based authentication.
12. Explicit service API calls into the SecureParser module shall allow the implicit assumption of operator roles.
13. The SecureParser module includes the following operational and error states: Power on/off state; Crypto officer state; User state; Self-test state; Error state; Key/CSP Entry state.
14. Recovery from error states are possible by power cycling the module.
15. Secret keys, private keys, and CSPs are protected within the cryptographic module from unauthorized disclosure, modification, and substitution.
16. Public keys shall be protected within the cryptographic module against unauthorized modification and substitution.
17. An Approved DRBG (SP800-90A CTR\_DRBG with AES-256) are used for the generation of AES cryptographic keys within the module.
18. An Approved DRBG (SP800-90A CTR\_DRBG with AES-256) are used for the generation of RSA cryptographic key pairs within the module.
19. Compromising the security of the key generation method (e.g., guessing the seed value to initialize the DRBG) requires as least as many operations as determining the value of the generated key.
20. The SecureParser module associates all cryptographic keys (secret, private, or public) stored within the module with the correct entity (KeyID) to which the key is assigned.
21. The SecureParser module provides a method to zero all plaintext secret and private cryptographic keys and CSPs within the module in a time that is not sufficient to compromise the plaintext secret and private keys and CSPs (service: module\_destroy).

22. Power-on Self-tests do not require operator intervention, they will be performed automatically when the module is initialized.
23. The cryptographic module performs the following self-tests:
  - a. Power up Self-Tests:
    - i. Software cryptographic algorithm tests:
      1. DRBG KAT, covers AES Encrypt
      2. AES Decrypt KAT (ECB mode with 256-bit key)
      3. AES Encrypt and Decrypt KAT (GCM mode with 128,192, and 256-bit keys)
      4. HMAC KATS using SHA-1, SHA-256, SHA-384, SHA-512, covers SHA-1, SHA-256, SHA-384, and SHA-512 hashing
      5. RSA-PSS sign/verify
      6. RSA encrypt/decrypt
      7. ECDSA sign/verify
    - ii. Software/Firmware Integrity Test – RSA public key verification of a private key signature. Covers all module executables listed in **Figure 1 - Image of the Cryptographic Module**.
  - b. Conditional Self-Tests:
    - i. Continuous Random Number Generator (RNG) test – performed on each sample from the DRBG (each sample will be 128 bits).
    - ii. Pairwise consistency test – performed each time an RSA “import” key pair is generated inside the module.
24. If the SecureParser module fails a self-test, the module enters an error state and output an error indicator via the status output interface.
25. The SecureParser module, does not perform any cryptographic operations while in an error state.
26. When the power-up tests are completed, the results (i.e. indications of success or failure) shall be output via the “status output” interface.
27. The operator shall be capable of commanding the module to perform the power-up self-tests at any time by power cycling the cryptographic module.
28. None of the mentioned hardware, software, or firmware components will be excluded from the module.

This section documents the security rules imposed by the vendor:

1. An approved encryption mode and an approved integrity mechanism must be requested by calling applications to run the SecureParser module in FIPS Approved mode.
2. Workgroup keys shall be mandatory for the SecureParser module to run in a FIPS Approved mode.
3. Workgroup keys shall not be placed in data shares.
4. The SecureParser module shall encrypt all share data using AES session keys.
5. The SecureParser module shall provide for the integrity of encrypted data shares using HMAC-SHA1, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512, or GCM. In addition an optional configurable second layer of integrity will be provided using either HMAC-SHA1, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512, ECDSA, or RSA.
6. All Secret and Private Keys entered via the module's `keystore_addKeyFromBuffer( )` service are encrypted using RSA key encapsulation. All Secret and Private Keys entered/output via the module's `parser_parseData( )` and `parser_restoreData( )` services are encrypted using Key Wrapping.

7. On Android Operational Environments, the calling application must wait a minimum of one minute from initial device power-up before invoking any module services. This ensures that the entropy pool in the Environment has gathered sufficient entropy to seed the module's DRBG.

## **7. Physical Security**

The requirements of Section 4.5 of FIPS 140-2 Physical Security are not applicable as the SecureParser is a software-only module which operates on a general purpose computer.

## **8. Mitigation of Other Attacks Policy**

The SecureParser module has not been designed to mitigate any specific attacks.

## 9. References

OpenSSL: This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit. (<https://www.openssl.org>)

## 10. Definitions and Acronyms

### **Share**

A partition of data created after the SecureParser is enacted to parse data.

### **Mandatory Share**

A mandatory share is a share that must be present for the proper recovery of data. In other words, all mandatory shares must be available. The number of mandatory shares is denoted by L.

### **Non-mandatory Share**

The SecureParser allows for the reconstruction of data with a subset of non-mandatory shares. The number of non-mandatory shares is denoted by N and the number of non-mandatory shares that must be available to restore is denoted by M.

### **M of N**

In this document, we refer to M of N shares which are intended to mean M of N non-mandatory shares and L mandatory shares. For example, “without M of N shares...” means without at least M non-mandatory shares and L mandatory shares.

### **Trusted**

Something that is trusted is known to meet its security assumptions. For example, a trusted share is known to be valid, untampered with, and otherwise uncompromised by any adversaries.

### **Workgroup key**

This can be any encryption key that can be used to encrypt or decrypt data. Often it is a shared key between users of the application working together.

### **Integrity Authentication key:**

This can be any key used for generating or verifying a MAC or signature of data.

### **Information Dispersal Algorithm (IDA):**

An algorithm, possibly keyed, that divides information into multiple components. An IDA may add redundancy to allow the information to be recovered if some of the components are unavailable. Each IDA has an inverse algorithm that, when given some or all of the aforementioned components, produces the original information.
